Coraopolis, Pennsylvania

Thursday,
March 29, 2007

The parties met, pursuant to the notice, at
9:10 a.m.

BEFORE: LINDA F. ZEILER
Designated Federal Officer

ATTENDEES:

Panel Members:

DR. JURGEN F. BRUNE
Chief, Disaster Prevention and Response Branch
Centers for Disease Control
National Institute for Occupational Safety
and Health
Pittsburgh Research Laboratory
Pittsburgh, Pennsylvania

DR. FELIPE CALIZAYA
Associate Professor
University of Utah
Mining Engineering
Salt Lake City, Utah

DR. JAN M. MUTMANSKY
Professor Emeritus of Mining Engineering
The Pennsylvania State University
University Park, Pennsylvania

Heritage Reporting Corporation
(202) 628-4888

ATTENDEES: (Cont'd)

Panel Members:

DR. JERRY C. TIEN
Associate Professor
Department of Mining Engineering
University of Missouri-Rolla
Rolla, Missouri

THOMAS P. MUCHO
Thomas P. Mucho & Associates, Inc.
Mining Consultancy
Washington, Pennsylvania

DR. JAMES L. WEEKS, Director
Evergreen Consulting, LLC
Silver Spring, Maryland

Staff Members:

MATTHEW WARD, Esquire
JENNIFER HONOR, Esquire
Office of the Solicitor
U.S. Department of Labor/MSHA

TERRY BENTLEY
Acting Special Assistant to the Administrator
DOL/MSHA, Coal Mine Safety and Health
Chief of Safety
Safety Division

MIKE HOCKENBERRY
Fire Protection Engineer
MSHA Technical Support

HARRY VERAKIS
Senior Projects Engineer
MSHA Technical Support

HAZEL HAYCRAFT
Management and Program Analyst
MSHA Technical Support

DEBRA JANES
Regulatory Specialist
MSHA Office of Standards, Regulations and
Variances

Staff Members: (Cont'd)

ROBERT TIMKO
Manager,
Dust and Diesel Monitoring Team, NIOSH

Presenters:

MR. ROBERT KROG, NIOSH

DR. FRED KISSELL, NIOSH (Retired)

MR. THOMAS MCNIDER
James Walters Resources
On behalf of the National Mining Association
Birmingham, Alabama

(9:10 a.m.)

3 MS. ZEILER: Good morning. I think we are
4 ready to start. I have one announcement. If you have
5 not signed in this morning, if you please could at
6 some point. Even if you were here yesterday, you need
7 to sign in for attendance today. Thanks.

8 We are going to start out this morning with
9 kind of a completion of the discussion of flammability
10 testing. Harry Verakis from MSHA is going to give a
11 presentation on MSHA laboratory scale flammability
12 testing. Harry.

13 MR. VERAKIS: Good morning. Before I get
14 into my presentation, there were a couple of things
15 that came up yesterday, and one of the questions was
16 from Jim Weeks. When Dr. Lazzara was making his
17 presentation, you mentioned about the 2G test, MSHA's
18 acceptance test, and what purpose did it serve.

19 If you go back -- and remember in the first
20 meeting that I talked about the development of testing
21 for fire resistant belting, and the incident that
22 happened in Great Britain, the Creswell fire, which
23 killed 80 miners, and then the British got into
24 developing tests for fire resistant belting, and then
25 of course the U.S. got in at that time, too.

1 And what the 2G or now the 18.65 test
2 resulted in was getting rid of the highly flammable
3 rubber belts. That's really what the purpose was of
4 it.

5 But you could see from presentations that
6 were made yesterday and work that has been done
7 overall -- I mean, there are other tests that are up
8 here as far as fire resistance high, and the 2G is
9 down near the bottom.

10 DR. WEEKS: Near the bottom.

11 MR. VERAKIS: Basically at the bottom, in
12 terms of fire resistance, compared to the other tests,
13 like the British have, the propane gallery test.

14 DR. WEEKS: Do you think that there is a
15 need for more rigorous testing?

16 MR. VERAKIS: I think you have plenty of
17 rigorous testing that has been done. I mean, you look
18 at the work that has been done at Lake Lynn. A lot of
19 tests done at Lake Lynn on a large scale.

20 DR. WEEKS: Right.

21 DR. WEEKS: I was thinking in terms of --

22 MS. ZEILER: Jim, could you please pull the
23 microphone over? Thanks.

24 DR. WEEKS: Sure. I was thinking in terms
25 of regulations requiring more rigorous testing, and

1 requiring that. And where the question came from for
2 Chuck was that we have seen fires that have occurred
3 in mines, and those belts had passed the tests, and
4 the question arose that what failed if they had passed
5 the test, and what does that mean as far as reasonable
6 expectations.

7 And it seems to me that if a belt passed a
8 test for flammability, then we should not expect fires
9 from that belt, but that happened, and so that is
10 where that question came from.

11 MR. VERAKIS: Yes. Now in fires that have
12 occurred -- and not in every instance, but in some of
13 the instances, we get samples of the belt from a fire
14 incident, and we run the 2G test on them.

15 There are a number of times, and many times
16 really, when the belt passes that test. There are
17 sometimes when it does not.

18 DR. WEEKS: What can we expect from a belt
19 that passes the test?

20 MR. VERAKIS: Basically what you can expect
21 is what the criteria for that test is. It is based
22 upon that particular test and what that criteria is
23 for that belt to pass that test.

24 DR. WEEKS: Well, there aren't many propane
25 lamps underneath belts in coal mines. So the question

1 is whether or not that simulates real conditions in a
2 mine.

3 MR. VERAkis: The 2G test?

4 DR. WEEKS: Yes.

5 MR. VERAkis: I never came across any data
6 that showed large scale testing before the 2G test was
7 developed. Here is a body of data from large scale
8 testing, regardless of what kind of large scale
9 testing it was, and here is a body of data from a
10 large scale test work, and from that test work here is
11 the 2G test, which was developed, and I have never
12 seen that body of data.

13 DR. WEEKS: Well, a good response to the
14 fire testing and the 2G test, but that was 50 years
15 ago, and can we do better now is the question, and I
16 think that is the question that I think we have to try
17 to answer.

18 MR. VERAkis: Yes, I think that is part of
19 this whole process, is that is the purpose. When I
20 get into my presentation, I will talk a little bit
21 about developing tests, and what it takes to get some
22 of these tests done.

23 MR. MUCHO: You mentioned a point, Harry,
24 that I would like to get clarified. You say sometimes
25 from belt incidents of fires in the U.S. that you get

1 samples back to Approval and Certification, and you
2 run the 2G test on them.

3 And you said that in some instances you will
4 find that they don't pass the 2G from the actual belt
5 that was involved in the fire. So, I assume the 2G --
6 and this is an assumption, and correct me if I am
7 wrong -- the 2G is fairly repeatable.

8 When you sample a type of belt for approval,
9 it is fairly repeatable and you get the same result;
10 is that correct?

11 MR. VERAkis: That is a difficult question
12 to answer, because you have such a variety of belts
13 and you have a belt that comes out of a mine from a
14 fire, it could be a warning on what the extent of the
15 wear is. Repeatability in fire testing is a difficult
16 thing to get the same answer.

17 You know, it is not like a chemical
18 analysis, and where you hope to get the same answer
19 all the time. I mean, you are dealing with dynamic
20 phenomena. So, repeatability, you don't expect in the
21 2G test to take a sample and get the same number every
22 time.

23 And in my presentation, I will talk about
24 that as far as the BELT test goes. One of the things
25 that we did with the 2G test quite some time ago was

1 to try to come up with a standard material, where we
2 could run this standard material before we actually
3 ran the test, to make sure that things were where they
4 were supposed to be, and you had things set up
5 properly.

6 I could not come up with a standard, a so-
7 called standard material, that I got the same number
8 every time. There is variations in it.

9 MR. MUCHO: Well, where I was headed really
10 was quality control. Is in some instances quality
11 control an issue, and I think if I understand what you
12 are saying, it is more often probably the belt and the
13 conditions that it was exposed to during its time and
14 use in the mine, and are factors which would
15 contribute to the results of the 2G test, or failing a
16 2G test; is that correct?

17 MR. VERAKIS: Yes, those can be factors.

18 MR. MUCHO: I take it that you don't see
19 much of a problem in terms of quality control of belts
20 that you see getting back from mines, and at least in
21 starting out, you think they are the same as belts
22 that were tested originally to give the approval?

23 MR. VERAKIS: Yes. One of the other things,
24 too, is that there was mention yesterday about oxygen
25 index testing. Oxygen index testing is a type of

1 quality control test.

2 You will get a number, and it is a fairly
3 repeatable test, and we even looked at the oxygen
4 index test back when we were doing development work as
5 a possibility for quality control. And I know that
6 other organizations do use it for that purpose.

7 DR. WEEKS: There are other factors that are
8 important in testing. For example, frictional
9 ignitions are a very common pathway to starting a fire
10 and testing for frictional ignitions with belts. The
11 other issue is --

12 MS. ZEILER: I'm sorry, Jim, but could you
13 just move that microphone a little closer. Thanks.

14 DR. WEEKS: And the other issue is smoke
15 density, and that is a factor in a mine in terms of
16 escape, and so those are a couple of things that come
17 up as potential issues that we are concerned with, in
18 terms of mine safety, which the 2G has --

19 MR. VERAKIS: The 2G test is basically an
20 ignition type test. You don't get propagation values
21 from 2G tests like Dr. Lazzara talked about yesterday.
22 One other thing that I want to make, too, because
23 this has been brought up -- it was brought up at the
24 first meeting, and it was brought up yesterday in the
25 NIOSH presentation about fire suppression work.

1 Fire suppression work is ongoing. We have a
2 program with NIOSH, in partnership with NIOSH, that we
3 are working on to look at fire suppression systems on
4 conveyor belts, and then part of the reason is how
5 well do fire suppression systems work.

6 We are starting to look at dry powder, dry
7 chemical systems, and what the effect of air flow is
8 concerning those systems, because you are dealing with
9 belt air, and how does that affect a fire suppression
10 system when it goes off.

11 So we have a program working with NIOSH to
12 evaluate that on a large scale, and we have a 50 foot
13 conveyor structure, with a length of belting, six foot
14 wide belting, and we are simulating a drive drum
15 system, and putting in fire suppression systems on
16 this conveyor system and see what happens in covering
17 that 50 feet and how these things work.

18 So we are at the point of starting that. I
19 mean, it is an ongoing project, and we are not at the
20 point of providing data at this time. But that will
21 come.

22 MR. MUCHO: Is that just with dry powder or
23 are you going to look at water systems, too?

24 MR. VERAKIS: We want to look at water
25 systems, too.

1 MR. MUCHO: Currently that has been dry
2 powder?

3 MR. VERAKIS: Pardon?

4 MR. MUCHO: What has been done currently is
5 dry powder?

6 MR. VERAKIS: Yes, we started out using or
7 working with dry powder.

8 MR. MUCHO: Yesterday it was stated that
9 there were some issues with high velocities with dry
10 powder systems?

11 MR. VERAKIS: Yes. I mean, it was mentioned
12 about VP-8.

13 MR. MUCHO: Right, dry powder.

14 MR. VERAKIS: Yes. I am going to give you
15 an overview of what I am going to talk about. I am
16 going to talk about the timeline from 1989 to 2002.
17 Dr. Lazzara talked about the research work and brought
18 it up to 1989, and I am going to talk about the belt
19 test program that we had, and then I will talk some on
20 the rulemaking that we were into.

21 I will talk a bit about the mid-scale test
22 development, and what went into doing that, and a
23 voluntary belt test program that we had set up, and
24 what some of the results were of that belt test
25 program.

1 And then concurrent with the belt test
2 program, and following subsequent rulemaking, what
3 went on there. Just to kind of sum things up, as Dr.
4 Lazzara talked about yesterday, we had a large scale
5 fire test, and they were made over a range of air
6 flows.

7 We went from no air flow on up to around
8 1,200 feet per minute. We got quite a bit of data
9 from the large scale tests, but even prior to the
10 large scale tests, we did a lot of small scale test
11 work.

12 We took the 2G apparatus, and it is run at
13 300 feet per minute. We took that apparatus and we
14 ran it with no air flow to see what happens. If we
15 didn't have any air flow in the passageway, then how
16 does the belt burn.

17 And we collected data with no airflow, and
18 made modifications. We also even looked at a German
19 tunnel test apparatus, and we did a lot of work there,
20 and we got data from that.

21 But when we got into the large scale test,
22 and what happened with the small scale test work, is
23 that you have that test and you have this test. I
24 mean, where do you draw the line, and how do you know
25 what is good, and what is not so good, and that was

1 the difficulty.

2 And you make changes to the test and
3 you get data, but what does that data mean. How can
4 you use that data, and that is where our problem was,
5 and what we said was that we need to go large scale.
6 We need to see what is happening on a large scale, and
7 of course at the same time there was the belt air
8 issue and air velocities.

9 So we did two things. We were collecting
10 data to develop a small scale test, and also to look
11 at what the effect of air flow was. And, of course,
12 Dr. Lazzara talked about developing the new mid-scale
13 test for fire resistant conveyor belting, and I will
14 get into that in more detail.

15 But what goes into this mid-scale type of
16 test, and what you need to do, is when you have
17 scaling in a test, you have got a large scale test
18 scale, a large Lake Lynn scale testing, and you want
19 to take it down to something smaller that is workable,
20 because large scale testing takes a lot of time, and
21 takes a lot of effort, and takes a lot of money. It
22 is very expensive.

23 You have to consider the type, and the
24 strength, and the location of the ignition emission
25 source, and the kind of ignition emission source that

1 you are going to have, and Dr. Lazzara talked about a
2 couple of different ignition sources.

3 He talked about the fuel tray, and he talked
4 about the coal pile; and what about the size and the
5 location of the test sample? Are you going to have a
6 large test sample or are you going to have a small
7 test sample? What are you going to have?

8 And that was shown yesterday in the Phoenix
9 presentation about different sizes of belts for
10 different types of tests, and what are the air flow
11 conditions going to be.

12 Are you going to run it at no air flow, 300
13 feet per minute, a thousand feet per minute? Well,
14 what Dr. Lazzara showed yesterday was 300 feet per
15 minute, and the large scale work at Lake Lynn was
16 optimum.

17 And you have to consider the material, and
18 what is the test apparatus going to be constructed of.
19 What kind of materials, because that plays a role,
20 too.

21 What we wanted with the mid-scale test was
22 we wanted to come up with a test that gave comparable
23 results with the large scale tests, so that we had
24 some kind of scientific basis for the test that is
25 being developed.

1 So we used the large scale test results for
2 that purpose. One was for the test apparatus to be
3 easy to construct, and so that it is not time
4 consuming to build a test apparatus.

5 We want it to be simple to operate, and the
6 more complicated that it gets to operate a test
7 apparatus, the more difficulty you can have with the
8 apparatus, and the more things you have to go over.
9 So you try to simplify the operation of the apparatus.

10 And, of course, you want it to be
11 repeatable. Is it a good test, you know. Then you
12 have to get into the cost. I mean, do you want a
13 hundred-thousand dollar test, or do you want something
14 that is more reasonable than that.

15 Okay. The time line, 1989, when the Bureau
16 of Mines came up with the mid-scale test, we felt that
17 we needed to have a public meeting. We had a public
18 meeting at the MSHA Approval and Certification Center
19 to talk about the results, and that was held on
20 January 19, 1989.

21 And we discussed MSHA and the Bureau of
22 Mines' large and small scale belt flammability test
23 work, and went into the details, and talked about the
24 Lake Lynn program, and talked about the development of
25 the mid-scale test, and talked about the small scale

1 test work that we had done.

2 Then we presented what is MSHA going to do
3 and what are our future plans for this conveyor belt
4 testing. We now have this mid-scale test, and what
5 are we going to do.

6 So we decided, well, we will have a
7 voluntary program and we believe that this mid-scale
8 test is something that we can get into rulemaking
9 with. So what is the mid-scale test going to do? Our
10 intent was to take the 2G test or the 18.65 test and
11 replace it.

12 And what are we going to replace it with?
13 We are going to replace it with the test that the
14 Bureau of Mines developed based upon the Lake Lynn
15 work.

16 So we came up with a voluntary test program,
17 and we instituted this test program at the Approval
18 and Certification Center using the mid-scale test. We
19 made the first test on February 8, 1989. We tested a
20 lot of different conveyor belt constructions from
21 manufacturers that were tested with the new belt test.

22 All different kinds of construction, such as
23 rubber, PVC, composites, and there wasn't any charge.
24 We want to see how well this test performs, and we
25 want to give the belt manufacturers an opportunity to

1 have tests run on the BELT test, and different
2 compositions that they may come up with, and basically
3 in a development type of thing for the manufacturers.

4 So in this whole program, we got a large
5 database on different types of belt constructions that
6 would pass, and that failed this new mid-scale test.
7 And the data that we collected, and when the company
8 went in, a specific belt company came in with their
9 belt constructions, we gave them their test data.

10 And then what we did was we took all the
11 test data from the different companies, and we
12 provided that, and also incorporated it. It was not
13 identified specifically to companies, but was
14 identified as test data, and it was placed into the
15 rule making record.

16 Now just to go over what the BELT apparatus
17 involved, and you heard this several times before. It
18 is a test chamber that is approximately six feet long,
19 and it is a foot-and-a-half square, and it has got an
20 exhaust transition section connected to it.

21 It uses a natural jet burner for the
22 igniting source, and we have a steel rack that is used
23 to hold the belt, with the test sample in the BELT
24 test apparatus.

25 The belt sample, the test sample, is nine

1 inches wide, by five feet long, and air flow through
2 the tunnel is set at 200 feet per minute, whereas the
3 2G test is 300, and the BELT test is 200 feet per
4 minute.

5 And the burner that we used for ignition is
6 held on the sample for five minutes. Now what is the
7 criteria in this test? Well, what does it take to
8 pass the test? Well, we run three test trials, and if
9 there is any belt sample left, it means that a portion
10 of the belt sample left on the five foot sample is
11 undamaged, and then the belt passes the test.

12 In any of the three tests if you have a
13 complete burning of that five foot sample, it fails,
14 and there has been some pictures of the belt test
15 apparatus, and you have seen that, and this is the
16 apparatus here with a hood in the front to capture
17 combustion products that may escape from the tunnel.

18 This portion here was a scrubber that we had
19 built to help control the smoke that was given off
20 from the burning sample. Here is the igniting burner,
21 and as Dr. Lazzara mentioned, this was an impinged jet
22 burner.

23 This is what the test sample looks like,
24 five feet long and nine inches wide. And this is the
25 setup of the test sample in the tunnel. It is just a

1 steel rack and basically the belt sample is placed on
2 the rack and it is held down with cotter pins along
3 the edge.

4 And this is what the flame from that
5 impinged jet burner looks like to give you a rough
6 idea. Now this is a start up of a test on a conveyor
7 belt sample. You have ignition of the conveyor belt,
8 and the belt is ignited, and the burner is removed,
9 and the belt is burning.

10 The belt is propagating flame down the
11 sample holder rack, and then what do you have left?
12 Ashes in this particular case.

13 DR. BRUNE: Would this be a failed test?

14 MR. VERAKIS: Yes, it definitely would be a
15 failed test.

16 DR. BRUNE: I just wanted to make sure I
17 understand this.

18 MR. VERAKIS: This gives you an idea of a
19 belt that passes the test. I mean, you can see that
20 there is some burning, but not a whole lot of burning.
21 Now we went through this test program with 21 belt
22 companies.

23 We started the test program as I mentioned
24 in February of 1989, and we ran this program until May of
25 1994. So for better than five years, we ran this program.

1 And there were 21 belt companies involved, and also a
2 chemical company participated. They had a formulation
3 that they provided to us that they wanted tested.

4 And then the data that we collected from
5 over 700 individual samples, we ran more than 700
6 flammability tests. And what was the result? Well,
7 we lumped it together. We had rubber and composites,
8 and which was talked about yesterday by Phoenix about
9 PVG belting, which is basically a rubber type cover
10 and a polyvinyl core.

11 We had some of those types of belts that
12 were brought to us from the belt companies that we
13 tested, and then of course, different combinations of
14 rubber, and there was mention yesterday about
15 chloroprene rubber, which is a trademark really of
16 neoprene, and blends of different types of rubber.

17 And then of course we had different PVC
18 belting, and out of these tests, what we came up with
19 or what we found was that 95 of the rubber and the
20 composites passed the test, and on the PVC side, we
21 had 38. So we had a total of all the work that we did
22 that 133 had passed the test.

23 And what does the data look like? This is
24 just an example, and one of the things that you
25 consider, too, when you are doing this type of test

1 work is what happens long term. Do the samples
2 deteriorate on long term when you are doing testing.

3 Well, this is a chloroprene rubber belt. We
4 ran the first three tests, and we get 17-1/2 inches
5 damage. Here is the pass/fail line of 60. Twenty
6 months later, we run another sample of that belting
7 and we get 15. Twenty-one months later, 18. Thirty-
8 four months later, 18. This is almost three years.

9 DR. TIEN: I just want to make sure that I
10 understand. Does number one correspond to number
11 four, where the same belt was burnt? Is number one
12 and number four the same belts?

13 MR. VERAkis: Yes. This is the same belt
14 over a long period of time.

15 DR. MUTMANSKY: Harry, what did you do with
16 the belt in the interim period?

17 MR. VERAkis: Just stored it in the lab.

18 DR. MUTMANSKY: You just stored it in the
19 lab?

20 MR. VERAkis: Yes.

21 DR. MUTMANSKY: I was just wondering. Okay.

22 MR. VERAkis: So over almost a three year
23 period, you have got this kind of data. Now as I
24 mentioned earlier about the pass/fail belt test, if
25 you were to run the test as an approval test, you

1 wouldn't necessarily gather burn data.

2 It either goes the full way, or it doesn't
3 go the full way, and you leave some belting left. You
4 don't necessarily have to measure the belt length.
5 But that gives you some kind of idea what is happening
6 with the belting, and how well the test is performing,
7 and how well the belt is performing.

8 When we talk about repeatability of tests,
9 this was an issue. So what we did was we took a
10 composite belt, or actually a PVG kind of belt, and we
11 ran 30 tests on it.

12 We had a long length of that belt, and we
13 set up a sampling plan on how to cut the samples out
14 of that belt to run on the BELT test. And we ran 30
15 tests, and these are the kind of results that you got.
16 I mean, here is the pass/fail line, and here is the
17 average, about 28.

18 Rulemaking. When we had the meeting in
19 1989, we concurrently initiated rule making with the
20 voluntary belt test program. As has been mentioned
21 earlier, we ended up proposing a rule for testing and
22 approval of flame resistant conveyor belting with the
23 BELT test, and that proposal went into the Federal
24 Register on Christmas Eve of 1992.

25 We had a comment period once the proposed

1 rule was put in the Federal Register, and we had a
2 comment period that lasted for approximately three
3 months or so, to March 26, 1993.

4 And then we reopened the record at the end
5 of March of 1995, and there was a request to have
6 public hearings, and we held a public hearing on May
7 2, 1995, on the BELT test.

8 And then the record closed on June 5, 1995,
9 and again it was reopened at the end of October of
10 1995. There were some issues that were brought up and
11 so we reopened the record to gather more information,
12 and the record was again closed on February 5, 1996.

13 Then another issue came up. There were
14 several issues along the way, or more than several
15 issues along the way with this rule making effort. We
16 opened the record back up again in 1999, and one of
17 the reasons there was because of the definition of
18 what are small mines.

19 At the time, we had defined a small mine as
20 being 20 miners or less. And then we had learned
21 where the Small Business Administration had said,
22 well, a small business is 500. So we had to do some
23 more work. And then the record closed after that
24 reopening on February 28, 2000.

25 Then in the semi-annual regulatory agenda

1 that came out, on May 13, 2002, the belt test was in
2 the final rule stage. We worked up the final rule for
3 that approval with the BELT test, and then there was a
4 notice in the Federal Register on July 15, 2002, that
5 that proposed rule was withdrawn.

6 So we have done what since that time? We
7 have not done any further rule making activity with
8 the BELT test. The work essentially stopped there.
9 And that's basically all that I have. Questions?

10 DR. MUTMANSKY: Why was the rule making
11 stopped? You didn't say why.

12 MR. VERAKIS: The reasons were given in the
13 withdrawal notice, and that we had AMS systems -- you
14 know, better detection of fires, and conveyor systems
15 were better, and improvements in the conveyor systems,
16 and improvements in the idler makeup.

17 And, of course, there was a reduction in the
18 belt fires, you know, from the time that we had
19 started this in the mid-'80s. I mean, that was one of
20 our concerns, is that there was an increase in belt
21 fires, and we were getting a lot of belting that was
22 burning up in these fires, and that was part of the
23 thrust for the rule making at that time, and where
24 there was a decrease in the number of fires.

25 DR. BRUNE: I assume that the rule making

1 did recommend that the BELT test would have to be
2 passed for a belt to be accepted or permitted for
3 underground use; is that correct?

4 MR. VERAKIS: That the rule making would do
5 what?

6 DR. BRUNE: That the rule making that was
7 proposed would have required that the BELT test was
8 passed in order for MSHA to permit that belt for
9 underground use; is that correct?

10 MR. VERAKIS: Yes.

11 DR. BRUNE: Would you still today think that
12 that is a rule that should be in place? I am putting
13 you on the spot now.

14 MR. VERAKIS: Well, yes, but I think that is
15 part of your committee's decision. I mean, it is
16 obvious from the work that Dr. Lazzara and myself have
17 done together on the conveyor belting, it is obvious
18 what our situation is, what our position is.

19 DR. MUTMANSKY: But we want to know what you
20 think.

21 MR. VERAKIS: What do I think?

22 DR. MUTMANSKY: Yes, sir.

23 MR. VERAKIS: Yesterday, Phoenix put up a
24 graph, a table basically, and I had mentioned it
25 earlier this morning, where you have tests from other

1 countries there, up here, high, in terms of fire
2 resistance, and you have the 2G test, which is
3 basically at the bottom.

4 Generally the world thinks that we are
5 leaders in this type of thing, and that we are going
6 to be on the top and we are going to have the best.
7 But based upon what was provided yesterday, that has
8 not been shown.

9 And you continue to have fires, and that is
10 the other problem. Yes, you can have monitoring
11 systems, and you can have fire suppression systems,
12 but as we know, these things can fail.

13 And your first line of defense is really
14 your conveyor belt. I mean, it doesn't take coal, and
15 it doesn't take wood to get the belt on fire. We had
16 a belt fire, and in which quite a bit of belting
17 burned up in it, and it was basically a bald entry.
18 There wasn't any coal in it.

19 We have had mines that have been closed.
20 Marianna, in 1988, the mine is sealed, and could not
21 be recovered. So it is not only the effect on the
22 miners and the mining industry, but it also affects
23 the community. The Marianna mine fire affected that
24 community.

25 And our goal was to come up with a better

1 test, and if it is going to be an improvement. If you
2 have failures in your monitoring system, and you have
3 failures in your fire suppression system, whether it
4 be a hope that you are not going to have a belt that
5 is going to burn very much.

6 And, yes, you have these other tests. You
7 have drum friction tests, and you have electrical
8 resistance tests. But when we had these increases in
9 the fires in the mid-'80s, and we knew what was going
10 on in the rest of the world as far as development for
11 fire resistant belting.

12 And we felt that the first thing that we
13 needed to do was to keep the conveyor from propagating
14 fire. If the conveyor belt propagates fire, then it
15 can catch coal on fire, roof coal, and catch the wood
16 supports on fire, and other things on fire.

17 And that was our main goal, was to limit
18 that flame propagation, and if we can contain that
19 flame propagation, we have a better chance of fighting
20 the fire, too, and less chance of that fire getting
21 out of control, and that was our main effort.

22 DR. BRUNE: Do you recall if any of the belt
23 fires that you investigated after the BELT test was
24 established, did you do any post-fire testing of the
25 belt involved and find out if it would have passed the

1 BELT test?

2 MR. VERAkis: No. Once the rule making
3 stopped in 2002, we didn't do any further work really
4 with the BELT.

5 DR. TIEN: Now there has been quite a few
6 years since the BELT test, and also the rule making
7 stopped a few years ago.

8 MR. VERAkis: Yes.

9 DR. TIEN: Do you have any second thoughts
10 as far as the standards for the BELT and if you are
11 going to re-initiate it again, or a modification, or
12 different things that you would do on the criteria?

13 MR. VERAkis: Would we make changes to it?
14 I don't think overall that we would make changes.
15 There might be some minor changes. One of the things
16 that we would want to keep is the comparability
17 between the BELT test and the large scale test work
18 that was done at Lake Lynn, because that gives you a
19 foundation.

20 It gives you a scientific foundation for the
21 test, and when you start tinkering with the test and
22 making changes here and there, and others have done
23 this -- the British have done this, and the Canadians
24 have done this, where they have made modifications.

25 And it was mentioned yesterday about the

1 propane gallery test, and the comparison between the
2 BELT test, and some modifications that were made to
3 the BELT test so that the BELT test would compare with
4 the propane gallery test.

5 Well, our goal was to have the test compare
6 with the Lake Lynn test, meaning if we would start
7 tinkering now to change things on it that we could
8 lose that comparison. We don't know exactly how that
9 goes.

10 DR. TIEN: Yes, that makes sense. The last
11 test you had done was for 700 samples or 700 tests.
12 Only 133 passed?

13 MR. VERAkis: Yes.

14 DR. TIEN: Would the improvement, I presume,
15 over the years in the use, do you think the same
16 numbers and the same ratio might hold this time?

17 MR. VERAkis: No. I think it would be
18 better. I mean, the 133, you have to remember that we
19 did over 700 individual tests, but on the pass/fail
20 basis, that is based upon three tests, because that is
21 the criteria for the BELT.

22 So you have 133 times 3 or so, but I think
23 today that the results would be different. There
24 would be more belting that would pass the test, and
25 the industry has a good idea of what the test amounts

1 to and so do some of the other organizations.

2 MR. MUCHO: Harry, at that time weren't they
3 playing with some formulations to pass the BELT test
4 as well?

5 MR. VERAKIS: Yes, there were all different
6 kind of formulations. There were belting samples that
7 were brought into us, where we only ran one test.
8 Belting companies would make up a formulation, and
9 they would bring that formulation into us.

10 We would run one test and the first test
11 failed, and there is no need to go any further. So it
12 was really development, too, for the belting
13 companies. You know, what kind of composition and
14 changes, and so forth, that they needed to make in
15 order to pass the test.

16 DR. CALIZAYA: You were talking about the
17 Small Business Administration, and the definition of
18 small mines. Could you further explain that?

19 MR. VERAKIS: The issue was that we had
20 defined that the small mines were 20 persons or less,
21 and then the issue came up, well, in your numbers, in
22 figuring out your economic analysis, how many small
23 companies you had and we were using a number of 20 or
24 less.

25 And it came back that the Small Business

1 Administration uses 500 as a small company, and so we
2 had to deal with that definition, and then you had to
3 go back and redo your economic analysis, and what the
4 impact is going to be.

5 MR. MUCHO: Harry, one question, and maybe
6 this would have been better for at least the panel to
7 participate in yesterday, but one of the issues that I
8 see before this panel is -- well, to set the stage, it
9 was just pointed out where the U.S. stands
10 internationally on the low rank in terms of fire
11 resistance testing for belts.

12 Obviously as you pointed out, the U.S. is
13 not the leader, and we don't necessarily want to be
14 the leader, but we wanted to at least have a system
15 that ensures health and safety, and the elimination,
16 if not the elimination of the minimalization of the
17 hazard of belts catching fire.

18 So this then says, well, what sort of a
19 testing procedure should we have, and you and Dr.
20 Lazzara made the point about the BELT test, and the
21 fire propagation.

22 The problem is that in the U.S., we don't
23 have the experience with the broad range of tests that
24 are used internationally, and the variations of them
25 even in the drum friction test, for example, there are

1 variations between different countries in that test,
2 and how it is performed, and really the results also
3 in terms of what they yield.

4 So things as we mentioned, the electrostatic
5 testing, and you mentioned this morning the oxygen
6 index test. It might be a good quality control test.
7 So there is this pourporri of tests out there that
8 are being done internationally, and without our
9 experience in the U.S. for this panel to start looking
10 at what might be the level that the United States
11 might want to be at, it gets a little bit difficult in
12 dealing with some of these other tests.

13 I think we have a good feel for the belt
14 test, and what that is going to give us, but some of
15 the other ones is a little more problematic for this
16 panel based on the lack of U.S. experience with these
17 tests, and the results that they yield, et cetera.

18 MR. VERAKIS: And there was work done by the
19 British concerning their tests, versus the BELT test,
20 and I take it that that was mentioned by Fenner-Dunlop
21 yesterday on the work that was done there, and what
22 kind of comparisons you get from the BELT test and the
23 propane gallery test.

24 And, of course, the Europeans, as far as the
25 standards for the European community, they were

1 dealing with the same kind of issues, because as was
2 mentioned by Fenner yesterday on what happened with
3 the propane gallery test, and how you come up with a
4 stalemate.

5 You know, this country test has their test,
6 and this other country has their test, and they are
7 comfortable with their tests, and they don't want to
8 make changes and modifications.

9 And basically what I am getting from you is
10 that you are in a similar situation that we were in
11 during the mid-'80s. We have these number of
12 different tests out there, and what are we going to
13 do. How are we going to make improvements to the
14 tests that we have. What are we going to choose.

15 And the way to look at this basically from
16 the scientific view, you have to have a basis, because
17 there are times when you have these tests, and you try
18 and go back and relate them to some kind of scientific
19 basis, and you don't have it.

20 You develop an apparatus, and you run a
21 bunch of tests that say here it is, and we have drawn
22 this line, and this is what you have to do to pass the
23 test, and there it is.

24 And that has happened -- I mean, if you were
25 to go back and we have had this difficulty with the

1 drum friction test, and if you go back and look for
2 the large scale test work, and the drum friction test
3 is not a small scale test. It is on the mid-scale
4 size.

5 You know, where does the data come from, and
6 what has it done, and that is where you have some
7 difficulty. What was the large scale work that was
8 done to say, well, you need this kind of drum friction
9 test. We had trouble dealing with that. We could not
10 find that kind of data.

11 DR. WEEKS: Well, the scale of the test is
12 one issue, but I think the more pertinent issue on the
13 drum friction test is that is a very common source of
14 the belt igniting, and if we are going to test belt
15 ignitions, how do we do that. If belt ignitions are
16 caused by belt frictions, how do we do that.

17 It seems to me that the drum friction test
18 may have its weaknesses, but it pertinent to that
19 particular problem, whether it is done on a small
20 scale or a large scale, and that's why the drum
21 friction test is pertinent.

22 MR. VERAkis: Yes, that is supposedly the
23 basis, but when you are going back and looking at the
24 drum friction test, and then as Dr. Lazzara mentioned
25 yesterday, if you have lagging on the drum, it is not

1 like the drum friction test that is running on a steel
2 drum. It is not the same.

3 So you have to deal with those kinds of
4 things. I understand that it is --

5 DR. WEEKS: Well, friction is a common
6 source of ignition, and how do we develop a test to
7 simulate that in the laboratory so that we can put
8 belts out there that don't ignite by friction, and
9 that is the issue.

10 And if wrapping a belt around an idler won't
11 do it, then what will. I mean, that is the problem
12 right there, how do we prevent friction on the
13 rotation of the belt, and there is a lot of ways to do
14 that. Even belt maintenance is one.

15 MR. VERAKIS: Well, yes, to make sure that
16 the belts are aligned so you don't get rubbing on the
17 structure, because that has been a source, too.

18 DR. WEEKS: The question is how do we
19 prevent that kind of event from happening, and the
20 drum friction test is one, and there are other ways of
21 doing it, but you at least want to try and address the
22 problem.

23 It seems to me that the BELT test addresses
24 the issue of flame propagation, correct?

25 MR. VERAKIS: Yes.

1 DR. WEEKS: And it is a very pertinent
2 issue, but it is not the only issue. There are other
3 issues.

4 MR. VERAKIS: Certainly, yes. It is not
5 addressing the frictional ignition issue. It is
6 addressing as you mentioned the flame propagation
7 issue.

8 DR. MUTMANSKY: Harry, Tom used the word
9 pourporri, and that sort of kind of brought some sort
10 of negative feelings about in this sense. Wouldn't it
11 be better if there was more standardization in
12 testing?

13 You see if the German tests are different
14 than ours, and the Australian tests are different than
15 ours, and then if that is the case, then the belt
16 manufacturers have a terrible problem. They have to
17 meet all three.

18 And it would really be nice if we could
19 somehow get together more internationally to come up
20 with well established standard test procedures, and
21 when we are looking for a new test procedure, we don't
22 start from scratch, but we try to meld our test
23 procedures with other countries so that the
24 manufacturers at least have a more centralized target
25 at which to aim their products. Has anything ever

1 been done on an international basis along these lines?

2 MR. VERAKIS: Not quite in that fashion. I
3 mean, we worked with the British when we were doing
4 the Lake Lynn work and developing the belt tests. We
5 worked with the British on the tests. We knew what
6 kind of tests the British had.

7 The Canadians worked with us, CANMET, and
8 they came and saw our apparatus, and actually they
9 built the apparatus in Canada, and they also built the
10 apparatus in England, the BELT apparatus.

11 And then the Australians, who we did some
12 work with, we had contacts with them. But not as a
13 unit of all of these different factions. And, yes,
14 that is certainly -- I think that is an admirable
15 goal, is to have universal tests, because certainly
16 the belt manufacturers have to deal with the different
17 country's tests.

18 But it is a difficult thing as you saw
19 yesterday with the Europeans, and trying to
20 standardize this. But it is certainly something that
21 should be done. But really from my personal opinion,
22 is that you have to have a scientific basis for it,
23 and it has to be as realistic as you can possibly have
24 it.

25 So you naturally work on a large scale, and

1 you go from there. But I would suggest that you look
2 at the work that the British have done in comparison
3 to the two tests, and that will give you some idea how
4 the BELT test compares with their tests, and the same
5 thing with the Canadians and the work that they have
6 done, and the work that the Australians have done, and
7 we can provide you with that information in papers.

8 DR. WEEKS: I just have one other question,
9 and it is very broad in scope and I guess the '89 to -
10 - well, the rule making was started in '89, and you
11 said there were a number of issues along the way, and
12 you mentioned the Small Business Administration
13 problem. What were some of the other issues?

14 MR. VERAKIS: There were issues like the
15 repeatability of the test. There were issues about --
16 and what was talked about yesterday, combustion
17 toxicity.

18 DR. WEEKS: Combustion toxicity in what
19 sense?

20 MR. VERAKIS: How do fire resistant
21 materials compare with non-fire resistant materials as
22 far as combustion and toxicity. So you have a more
23 fire resistant belt than your current standard, and
24 does it create a more toxic problem for you.

25 DR. WEEKS: How did you deal with the issue

1 of that and what was your approach to that?

2 MR. VERAkis: Well, one of the things is
3 that we had a lot of tests with the BELT test, and
4 showed testing over a long period of time, and when
5 you get into flammability testing, there is always
6 that difficulty about repeatability because you are
7 dealing with a dynamic phenomena.

8 I mean, you have operator dependency, and
9 you have got materials that may not be completely
10 uniform. As I mentioned earlier, we tried to come up
11 with a standard for 2G, and that was a difficult thing
12 to do.

13 DR. WEEKS: Well, for example -- I mean,
14 with the variability from the tests, I mean, one would
15 conclude that you would just take a lot of tests and
16 an increase in number. I mean, for example, if a belt
17 test had gone into effect, would you require something
18 like 20 tests and you had to pass all 20 in order to
19 meet the requirements?

20 MR. VERAkis: No, we would have stuck with
21 the three.

22 DR. WEEKS: Three?

23 MR. VERAkis: Yes.

24 DR. WEEKS: And they would have had to pass
25 all three?

1 MR. VERAKIS: Yes, they would have had to
2 pass all three, but if that test was instituted and
3 that was going to be our approval test, then what we
4 would have done is as things went down the road, we
5 would have taken samples from the industry and checked
6 them out and see how well things are going.

7 DR. WEEKS: What was your solution to the
8 toxicity problem?

9 MR. VERAKIS: The toxicity problem is a
10 complicated issue. One of the things that we did is
11 that we looked at the work that the National Bureau of
12 Standards had done, and the National Bureau of
13 Standards had done work comparing non-fire resistant
14 materials to fire resistant materials, and what were
15 their findings.

16 And from that work, their findings weren't
17 that fire resistant materials were more harmful than
18 the non-fire resistant materials. There wasn't
19 anything that stood out that said that fire resistant
20 materials are bad as far as combustion toxicity goes.

21 You are going to have less material burning,
22 and you have less of the material into the atmosphere.
23 So from their point of view, that wasn't the problem,
24 and if you go back and you look at other things, and
25 you look at the -- let's take something like

1 children's sleepwear, you know. We have got fire
2 resistant children's sleepwear.

3 DR. WEEKS: We don't find much of that in
4 mines.

5 MR. VERAKIS: No, you don't, but there are
6 other materials where you use fire retardants that are
7 similar that you use in conveyor belting.

8 DR. WEEKS: Well, the issue here for us is
9 if we come along and say we should reinstitute the
10 BELT test, I just want to know what it is that we are
11 suggesting. For example, if you had said, yes, we
12 have to have 20 tests in order to make it valid, that
13 makes it problematic.

14 And the toxicity issue from what I hear you
15 saying is not really a problem. I mean, there might
16 be different materials that come off of flame
17 resistant materials, but not from belts.

18 MR. VERAKIS: Right.

19 DR. WEEKS: So it does appear to be a
20 problem.

21 MR. VERAKIS: I don't consider it to be a
22 major problem, no.

23 DR. WEEKS: Were there other issues in that
24 13 year period that we should know about?

25 MR. VERAKIS: I think one of the things --

1 and I think we provided to you the public hearing
2 record that we had in 1995, and that gives you a
3 pretty good idea of what some of the issues were.

4 And it is also that you get into the
5 economics, and what is it going to cost. Questions
6 were asked yesterday about what is it going to cost,
7 and what is this new belting going to cost, and at the
8 time that we were working on the economic analysis for
9 the final rule work, and the numbers that we had, the
10 information that we had was that the range was
11 somewhere on the order of about 5 to 30 percent, 30 to
12 35 percent.

13 And you hear different numbers, like well,
14 it is going to be 50 percent, and it is going to be
15 40. But there were some companies that told us, well,
16 we can make a belt that passes that test, and there is
17 not going to be any cost differential. So there was a
18 range.

19 MS. ZEILER: Any more questions? If not,
20 thanks a lot, Harry, and I think we can take a 15
21 minute break at this point.

22 (Whereupon, a short recess was taken.)

23 MS. ZEILER: All right. I would like to
24 welcome Terry Bentley, who is here from MSHA's Coal
25 Mine Safety and Health to give a presentation on the

1 historical data on belt fires. Terry.

2 MR. BENTLEY: Good morning. Jan Mutmanský
3 just a moment ago came over and introduced himself,
4 and I introduced myself yesterday to Jim Weeks. So
5 let me introduce myself to the rest of the panel.

6 My name is Terry Bentley, and I am standing
7 in for Mike Kalich. Mike works for me. He is
8 currently acting as the Chief of Safety, and I am the
9 Chief of Safety for MSHA Coal Mine Safety and Health,
10 and have been for nearly four years, and currently I
11 am filling another role in headquarters. I am the
12 special assistant acting to the administrator right
13 now.

14 But Mike was detained. We have him on a
15 mine rescue rule right now, and we are trying to get
16 that thing perfected, and out the door hopefully
17 within the week.

18 So without further delay, I would like to
19 address a little historical perspective about reducing
20 belt fires in underground coal mines. One program
21 note for you folks, barring any unforeseen
22 difficulties, today at two o'clock the Aracoma report
23 will be released and posted on our website, and that
24 is current as of about 30 minutes ago, unless
25 something changes.

1 So if that is the case, that we do in fact
2 release it, copies will be distributed to you folks
3 before the meeting is over. Is that correct, Linda?

4 MS. ZEILER: That's right.

5 MR. BENTLEY: Talking about belt fires in
6 underground coal mines, one of the things of course
7 that I want to talk about is the maintenance aspects,
8 but looking back historically, many of the belt fires
9 can be attributed to maintenance type issues, and in
10 particular attributed to frictional heating, belt
11 slippage, and things like that, and welding in some
12 instances, and you will see that in the course of the
13 presentation.

14 Belt fires. You probably are aware that
15 there has been a change in the reporting requirements
16 for belt fires. Well, for that matter, for fires in
17 general.

18 Previously there was a requirement in the
19 regulations that a fire that was not extinguished
20 within 30 minutes, and as most of you may be aware,
21 because of the final Mine Evacuation Rule, which was
22 finalized on December 8 of last year, it is now a 10
23 minute reporting requirement.

24 And a belt fire is reportable to MSHA, of
25 course, if it causes a death or severe injury, and

1 takes now 10 minutes or more to extinguish after
2 discovery, and of course in accordance with the rules,
3 the fire must be reported within 15 minutes.

4 And to put that in perspective, because the
5 data that we have is actually based on the 30 minute
6 previous rule reporting requirement, because this is a
7 brand new rule, of course.

8 Some data that we had in 2003. For example,
9 selected year, three reportable fires, and 37 non-
10 reportable fires, and that of course is in accordance
11 with the 30 minute rule requirement.

12 A 25 year history of reportable belt fires
13 starting in 1980 through 2005, and you can see the
14 breakout. You may also notice -- and I think Harry
15 had made a reference to -- Harry Verakis had made a
16 reference to the 1995 period, which would be right in
17 this area here, and that belt fires had lessened in
18 that period of time.

19 So this does correlate pretty much with what
20 Harry said. As you can see in later years, there have
21 been additional fires that were reportable, somewhere
22 in the 4 to 5 range for a couple of years there.

23 In this chart, you can see belt fires
24 reported per thousand mines on the left here, and on
25 the right, of course, we have the number of active

1 underground mines. You do see a decrease under the
2 years from 1980 through 2005.

3 And since 2005, there has been an increase.
4 Not a dramatic increase with the production of coal,
5 but the underground mines are probably more in about
6 the 600 underground mines that are active and
7 producing, and we certainly have other mines that are
8 non-producing that we inspect in the presence of mine
9 personnel.

10 But give or take, it is in the 600 mine
11 range, the number 600. You can also see the rate of
12 entry of belt fires per thousand active mines, and you
13 can see the number of belt entry fires. And it is
14 kind of interesting.

15 There have not been that many reportable
16 again under the 30 minute rule, but as you can see, it
17 fluctuates, but not a significant number over any year
18 that would really in my view give you much of a
19 dataset in terms of a trend without a greater
20 population of mines.

21 So from 1980 until 2005, there were
22 reportable fires, 63, and I think it is significant to
23 point out that in that period of time there were no
24 fatalities in underground coal mines attributed to
25 belt fires.

1 And also there were no reportable lost time
2 injuries. Now we do know that there were some mine
3 fires where folks did experience some smoke
4 inhalation, but remember Part 50 requirements for
5 reporting, and just to touch on that a bit, someone
6 could be administered first-aid, and that is not
7 necessarily a reportable Part 50 accident if there is
8 no medical treatment. Also, if they return to work
9 the next day.

10 So we have no record of reportable lost time
11 to injuries in that 25 year period, nor any fatalities
12 between 1980 and 2005. And this information you may
13 notice down at the bottom was obtained -- and as well
14 as some of the other information that has been pulled
15 here from the MSHA Atmospheric Monitoring Survey,
16 which was done in 2003.

17 So historically belt entry fires, there have
18 been more damage to belt structures, the mine, and
19 infrastructure, and so forth, than there have been of
20 course for fatalities.

21 Obviously, we do know that the Aracoma
22 report will point to two fatalities in 2006, but
23 historically there have been much greater damage to
24 the mine infrastructure, belt structure, equipment,
25 and so forth.

1 You can also see the Aracoma picture in the
2 right-hand screen shot there, which does show some of
3 the belt structure that was damaged. Cause of the
4 belt fire, which is a non-injury event, does result of
5 course in significant cost. I don't have a dollar
6 figure for that. I am not an economist.

7 But obviously there is a substantial loss of
8 production days in many instances, and rehabilitation
9 costs can be very extensive, not only to replacing
10 electrical components, and belt structure, and
11 infrastructure, but also to the mine roof, which may
12 need extensive rehabilitation.

13 Mine rescue expenses, and extended work hour
14 for mine management. A major belt fire event is an
15 extremely costly event, even without any injuries.
16 Increasing trends. Obviously coal prices have risen,
17 and production has risen accordingly because there is
18 a tremendous demand.

19 And you can see charts again from 1980
20 through 2005 showing an increase in coal production,
21 and average cost of metallurgical coal, and coal
22 plants, and you see the various coal fields, the
23 Central Appalachian coal fields, and North Appalachia,
24 Illinois Basin, and the Powder River Basin, and the
25 Uneta Basin.

1 And as you can see all the prices have
2 risen, and for a period of time, they did peak, and
3 they have come down a little. Not dramatically.
4 There has been a great increase in push for
5 production.

6 For example, a long wall belt could
7 experience downtime, and this is 2002 figures, of at
8 least \$30,000 per hour, and you could certainly
9 extrapolate that and presume that that cost is much
10 greater now in 2007.

11 Obviously, larger mines do have longer belt
12 lines and larger belts certainly associated with
13 longwalls and increased production in general, and
14 there has also been a trend for fewer belt attendants,
15 and that would probably be attributed to increased
16 labor costs.

17 For example, 10 drives and 5-1/2 miles of
18 belt generally would be something typical of three
19 attendants per production shift. I can recall
20 previously when I was an inspector that most mines had
21 an attendant at every drive location, and was
22 responsible in many instances for only one section of
23 belt.

24 So obviously labor, and over time, the cost
25 of labor has risen, and that has impacted on the

1 number of belt attendants. And we talked a little bit
2 about preventing belt fires, which involves early
3 detection, and certainly maintenance in extinguishing
4 belt fires.

5 I can't say enough about proper maintenance
6 and examinations. I think that maintenance is very
7 important. Examinations are a critical part of belt
8 fire prevention. Without it, I think it is a
9 prescription for problems.

10 Fifty-six percent is a portion of accident
11 reports that have identified inadequate maintenance as
12 a contributing factor for reportable belt fires.
13 Again, this comes from -- no, I'm sorry, this does not
14 come from our AMS survey. This comes from MSHA
15 accident investigation reports for the reported fires
16 between 1980 and 2005.

17 An example of a typical roller, which caused
18 the fires and contributed to heat and friction. This
19 is another one, hot rollers and bearings from our
20 accident report data. Ten percent of reportable
21 accidents, and 63 percent of non-reportables.

22 Now the non-reportables do come from our AMS
23 survey, and is attributed to hot rollers and bearings,
24 obviously a significant maintenance issue. This is a
25 typical shot showing devastation and damages as a

1 result of a fire. Obviously you can see some
2 smoldering ambers still present there.

3 Another shot showing fire damage as the
4 result of a belt fire. Belt friction. According to
5 our data, friction along belts, 18 percent of
6 reportable fires were attributed to belt friction, and
7 six percent of non-reportable fires were attributed to
8 belt friction.

9 Friction at drives. Again, as you will
10 recall, I combine these together, as it is a
11 substantial amount. Friction at drives, 18 percent
12 reportable; and 8 percent not reportable.

13 And I alluded to welding and cutting
14 earlier, 10 percent reportable; belt fires, 8 percent
15 not reportable. Again, this is from the period of
16 1980 through 2005, a 25 year history.

17 So reported fire ignition sources, 18
18 percent of belt drives, friction; 18 percent friction
19 on long belts; 16 percent attributed to electrical
20 issues, including diesel and hydraulic grouped
21 together.

22 And eight percent attributed to cutting and
23 welding, and 10 percent attributed to hot rollers and
24 bearings, and 30 percent, which was a variation, all
25 lumped together indeterminable. So as you can see, a

1 lot of these fire ignition sources are clearly
2 maintenance related and probably in many, many
3 instances examination related.

4 Non-reportable fire ignition sources;
5 welding and cutting, 8 percent; 63 percent, hot
6 rollers and bearings; 8 percent, friction at drives;
7 and 6 percent, friction along belts, and 15 percent
8 attributed to electrical related issues; hydraulic,
9 diesel, and so forth.

10 And remember that these would fall within
11 the 30 minute non-reportable period under the previous
12 regulation, and this comes out of our AMS survey.
13 Obviously, atmospheric monitoring systems can play a
14 large part in detection of belt fires well before it
15 becomes a truly fire situation because of CO
16 detection.

17 However, proper installation and maintenance
18 is absolutely critical, and of course the proper
19 operation, and I would also add to that when you talk
20 about operation, you need to have very well qualified
21 AMS system operators on-hand, and they need to be
22 competent, and well trained, and knowledgeable, and
23 have the ability to make decisions and respond if they
24 have certainly alarm levels, and even at the alert
25 stage as well.

1 In 2000 and 2003, there was 32 non-
2 reportable fires, and 37 were detected by using the CO
3 monitoring systems in an 18 month period. That is
4 probably pretty indicative of the value of a CO
5 monitoring an AMS system if it is properly maintained
6 and properly used.

7 And of course the last resort, which we hope
8 we don't get to, is extinguishing the belt fires, and
9 I have already alluded to the cost, notwithstanding if
10 there are injuries or fatalities. Significant costs.

11 So in conclusion, we could say, yes, in the
12 near term belt fires have increased in frequency and
13 severity between 2002 and 2006, and I would again
14 point back to the value of adequate maintenance, which
15 significantly can and does prevent belt fires, and
16 certainly a factor in over half the fires from our
17 data.

18 And once again I would point to early
19 detection, well maintained fire suppression systems,
20 water pressures, and so forth, and fire fighting
21 equipment provided as the last line of defense, and
22 that concludes my portion of the presentation. Does
23 anyone have questions at this point?

24 DR. WEEKS: Initially, I have a question
25 about fire prevention. You talked about fire

1 prevention, and you didn't say about the composition
2 of the belts, and you mentioned about the maintenance
3 of the belts, but you didn't say anything about the
4 belt composition.

5 MS. ZEILER: Jim, could you move the mike
6 closer to you. We are having a difficult time hearing
7 you.

8 MR. BENTLEY: I think that is an important
9 aspect, and in my view, we certainly want to try to
10 prevent it through maintenance, but certainly flame
11 retardant belt properties would be highly
12 advantageous. There is no question about that. It
13 was not a part of this presentation.

14 DR. WEEKS: I know.

15 MR. MUCHO: Terry, I missed a part. The
16 non-reportable data, where does that come from?

17 MR. BENTLEY: It comes from our AMS survey
18 that was done by some folks in technical support from
19 records on the AMS systems of fires that did not rise
20 to the level that needed to be reported within 30
21 minutes.

22 MR. MUCHO: My question is how did MSHA
23 become aware of these incidents?

24 MR. BENTLEY: I didn't do the survey, but I
25 am pretty sure that it was given voluntarily by a

1 certain population of mining companies. I don't even
2 know if Harry knows the answer to that, but I do not.

3 MR. VERAKIS: So how do we get the non-
4 reportables for fires? As Terry has mentioned, there
5 are surveys carried out trying to gather this
6 information from mine operators, and looking at their
7 records, and taking that information, and see what is
8 happening out there.

9 MR. MUCHO: So is that from the AMS systems
10 where you had an alarm level, but not 30 minutes
11 duration? Is that where it is coming from?

12 MR. BENTLEY: Yes.

13 MR. MUCHO: Because they go to the hot
14 bearings, and so on, and there are many instances of
15 hot rollers, for example, and this 63 percent number
16 comes from something that induced an alarm level.

17 MR. BENTLEY: Inducing an alarm and
18 progressed to a fire at some point.

19 DR. WEEKS: If I could just follow up on
20 that. Was that survey done only of those mines that
21 had AMS systems in place?

22 MR. BENTLEY: I don't think it was done in
23 all mines that had AMS systems, but just a selected
24 number, and again coal mine safety heath didn't do it.
25 Tech support did it. So I would have to defer to

1 someone in tech support on that point. Bill Francart
2 assembled a lot of this data, and Bill is not with us
3 today.

4 MR. VERAKIS: We can get that answer from --

5 MR. MUCHO: We have seen the data, and it
6 was the AMS system mines, and so the data came from
7 all AMS system mines.

8 MR. BENTLEY: Right, and whether it was
9 everyone or not, I'm not sure. But it may have very
10 well been all of them.

11 MR. MUCHO: It was and the data has been
12 updated from 2003 to 2006, and that information has
13 been provided to the panel.

14 DR. WEEKS: But as far as the reportable
15 fires, were those that are in the Part 50 dataset; is
16 that correct?

17 MR. BENTLEY: That's correct, that were not
18 extinguished within 30 minutes.

19 DR. WEEKS: And so that would include in the
20 common denominator all mines, and those in the Part 50
21 dataset.

22 MR. BENTLEY: I think you would be correct,
23 yes.

24 DR. WEEKS: But the nonreportables only
25 focused on the data of those mines that had AMS, and

1 so it is a much smaller denominator.

2 MR. BENTLEY: Because there would be no
3 other record of the population of AMS systems.

4 DR. WEEKS: So the implication is that the
5 number of non-reportable fires is larger?

6 MR. BENTLEY: I think you could make that
7 presumption and be correct, yes. The number we
8 wouldn't know.

9 DR. TIEN: Terry, you mentioned that you
10 were an inspector before?

11 MR. BENTLEY: I was an inspector in Hazard,
12 Kentucky, and I came to MSHA in 1982, and I was an
13 inspector there for about 5-1/2 years or so.

14 DR. TIEN: I am just curious. As you are
15 doing routine inspections do you look at the AMS as
16 part of your record?

17 MR. BENTLEY: Yes, as part of the regular
18 health and safety inspection. I will have to tell you
19 that when I was inspecting there were no AMS systems.
20 I worked in District Seven, which is Hazard,
21 Kentucky, and headquartered out of the Barbourville
22 District Office, and then in 1988, I went up to the
23 Anthracite Region for about 8 years, and in 1996, I
24 went out to our Illinois Basin.

25 I was a field office supervisor in

1 Pennsylvania, as well as a health supervisor, and then
2 in 1996, I was a special investigations supervisor for
3 criminal issues, civil issues, and discrimination
4 issues, as well as accident investigations.

5 Plus, I was a staff assistant to the
6 district manager at that time. I came to MSHA
7 headquarters in the fall of 2000 in the division of
8 safety as the deputy chief of safety, and not quite
9 four years ago, I became the chief of safety. So I
10 have been in MSHA since 1982, and it seems like it was
11 only a few days ago.

12 DR. TIEN: Since the nonreportable came from
13 AMS records, I assume those numbers would be pretty
14 accurate.

15 MR. BENTLEY: I believe it is, and I would
16 have to defer to Bill Francart on that. I guess we
17 can get that information. Bill provided us the data
18 for this presentation, and Bill is involved in an
19 accident investigation review right now.

20 Our folks -- we are spread pretty thin at
21 this point. There are only so many of us, and we are
22 wearing a lot of hats in the agency right now.

23 DR. WEEKS: We have sort of a practical
24 problem for this panel, and I share your concern about
25 mine maintenance, and we could write in our report

1 that operators to maintain their mines. I mean, it is
2 one of those statements that -- well, is there some
3 need for a ruling on maintenance, or is it a question
4 or enforcement, or is it a question of common sense,
5 or morality? I mean, what kind of issue is this?

6 MR. BENTLEY: You are asking me for my
7 opinion?

8 DR. WEEKS: Yes.

9 MR. BENTLEY: It is probably a combination
10 of all those probably that you touched on. Morality
11 or ethics. That may be a bit out of bounds.

12 DR. WEEKS: Well, I am not just asking you.

13 MR. BENTLEY: I know you are, and all those
14 considerations, and I think the point that you are
15 trying to make if I understand it is that a
16 responsible mining company would want to consider
17 maintenance as a very important part of a functioning
18 operation, because ultimately it translates into
19 production.

20 I think maintenance in general in many
21 instances is focused very much of course on the
22 production aspects, but when you talk about the
23 operation of a belt system, a belt conveyor system,
24 that in and of itself is extremely production related.

25 So I think in general that I would agree

1 with that, that it would be a range of factors. But I
2 would recommend to any mining company that maintenance
3 and prevention would be a key component of their
4 operational planning. And I think that for many, many
5 companies that it is, of course.

6 DR. GALIZAYA: Just to follow up on the same
7 issue about maintenance. I would like to know a
8 little bit more about procedures, and focusing on this
9 maintenance problem, and the actual procedures.

10 MR. BENTLEY: We have regulations that our
11 inspectors use during the course of an inspection
12 where they are not targeting maintenance, but that is
13 a result of enforcement, is better maintenance.

14 But I think that probably you are leading to
15 something like a specific policy or even a regulation
16 which would put more focus or impetus on
17 maintenance. Is that what you are saying?

18 DR. GALIZAYA: Yes, and training as a part
19 of that.

20 MR. BENTLEY: I think that training
21 absolutely would be a part of that. I think that the
22 proper training of personnel in the upper echelons of
23 mine management, and all the way through the
24 production folks, and maintenance folks, and down to
25 the rank and file miners, translating into the value

1 of preventive maintenance would be very important, and
2 would be useful.

3 DR. MUTMANSKY: On those 56 percent of belt
4 fires due to maintenance issues, would you be able to
5 identify what types of mining companies are most
6 normally associated with belt fires that are due to
7 maintenance issues?

8 Would they be big companies, small
9 companies? Is there any -- have you identified any
10 characteristics of those kinds of fires?

11 MR. BENTLEY: I don't think that was done,
12 and this would purely be speculation on my part. But
13 over a 25 year period, you could probably surmise that
14 earlier in the stage, in the period, would probably be
15 larger companies that have employed AMS systems.

16 AMS systems are more widely utilized now, of
17 course, and in smaller production mines. But still I
18 would say that it would be a medium to large size
19 company, as opposed to smaller companies that
20 generally don't use AMS systems, and go back to
21 detection for the point type sensor systems, heat
22 sensors.

23 MR. MUCHO: I don't know if that is as true
24 today, Terry. I think it started out that way and it
25 certain did in belt air lines, especially along the

1 long wall mines.

2 But looking at the most current data that we
3 have, certainly the mines that I am familiar with, I
4 was very surprised to see the number of small mines in
5 that.

6 And certainly the State of Pennsylvania
7 right now, the mines that are running AMS systems, and
8 using belt air especially, are non-long wall mines.
9 So it is a bit of a surprise and a bit of a change has
10 happened more recently, I think.

11 MR. BENTLEY: I think in the latter period
12 though that is absolutely true, as opposed to the
13 early part of, let's say, the 25 year period.

14 MR. MUCHO: The other thing that I want to
15 go back to is this 56 percent number on maintenance
16 that Jan was just talking about, and Jan used the
17 words fires due to maintenance issues.

18 Is that number related to maintenance wa the
19 cause, inadequate maintenance, or inadequate
20 maintenance was a factor?

21 MR. BENTLEY: Could you repeat that? I am
22 not sure that I understand the question since they are
23 both maintenance related.

24 MR. MUCHO: If you could go to that slide.
25 It is a contributing factor.

1 MR. BENTLEY: Yes.

2 MR. MUCHO: Which can be a very different
3 animal, and certainly in terms of magnitude as far as
4 being a key factor.

5 MR. BENTLEY: I would agree with that.

6 DR. WEEKS: The issue there is did you
7 control maintenance and not necessarily addressing the
8 root cause of belt fires.

9 MR. MUCHO: Well, the implication is that I
10 have a problem that causes a fire in a belt, and as I
11 walk along the belt, I find some other maintenance
12 issues that could have been there, and may have
13 contributed somewhat, and helped with the problem, or
14 may have been a non-factor.

15 So my root cause was maybe a hot roller or
16 bad bearing in the back, or something like that, and
17 that was my root cause, but in the meantime, there was
18 a misalignment or whatever. But they could be talking
19 about other kinds of maintenance issues, a whole host
20 of things.

21 MR. BENTLEY: Without the data, I am not
22 sure. But the only thing I can say is that it would
23 be a maintenance related issue, and no question of an
24 examination issue, too, and probably most of these.

25 DR. TIEN: Well, Tim, I had the same

1 question, and let's reverse the question. What are
2 the non-maintenance contributing to the fires, some of
3 the cases that you might think of.

4 MR. BENTLEY: That is a good question. I am
5 not sure that I know the answer. Non-maintenance
6 contributing fires.

7 DR. TIEN: Is it because of hot rollers, or
8 because of a lack of maintenance or improper
9 maintenance that caused the fire or is contributing?

10 MR. BENTLEY: Well, welding would be
11 maintenance and repair, and we have grouped it in with
12 those.

13 MR. MUCHO: You know, the electrical ones.

14 DR. BRUNE: A belt frame falls down because
15 of roof instabilities, and that is not necessarily
16 something that you can foresee and do something before
17 it happens.

18 MR. BENTLEY: No, unless -- and it is not
19 really a maintenance issue. In a broader sense it is,
20 but if the mine roof was not properly attended, or
21 support, that caused it. But I don't think that is
22 the maintenance that we are referring to here.
23 Overall mine maintenance, but not maintenance in the
24 sense of a well functioning belt system, belt conveyor
25 system.

1 MS. ZEILER: If there are no more questions,
2 thanks, Terry.

3 MR. BENTLEY: Okay. Thanks, folks, and
4 thanks again to the panel.

5 MS. ZEILER: I would just make a note that
6 at this point all the presentations by MSHA and NIOSH,
7 and the belt manufacturers on the issue of belt
8 flammability have been presented to the panel.

9 So at this point, if you would like to start
10 any kind of discussion, we could do that. It is up to
11 the Chair on how you would like to proceed for the
12 balance of the morning.

13 DR. MUTMANSKY: At this point in time, I
14 think it is important to get the panel reaction. I
15 would like to mention that last night at dinner, we
16 were discussing how we would proceed after all the
17 hearings have been held, and how we would form
18 subcommittees to address these various issues.

19 I would propose, however, that we may wish
20 to use tomorrow morning's time to discuss this
21 further, unless the panel is intent upon discussing
22 them at this particular time.

23 My reasoning in proposing this is that I
24 would like to hear more about the 1992 committee's
25 report and how some of those issues played out, and I

1 would think maybe it would be important for us to hear
2 what Dr. Ramani has to say about the 1992 report
3 before we begin serious discussion of belt
4 flammability issues.

5 But I would like to hear from the panel.
6 The panel may not agree with me, and that is just my
7 thinking on this.

8 DR. BRUNE: I don't know if this is the
9 appropriate time, but I had one issue that was
10 addressed in individual discussions, but I would like
11 to address it for the record.

12 I had some discussions with some of the
13 representatives from the manufacturers regarding
14 deterioration of belt quality, especially with respect
15 to flammability over time.

16 And I don't know if there is an opportunity
17 to ask the manufacturers representatives to address
18 this at this time, or do we have any other
19 opportunity?

20 MS. ZEILER: If they are comfortable
21 answering the question, they can answer it now, or we
22 could set something up for immediately after lunch if
23 you want to.

24 DR. BRUNE: Well, Mr. Kusel, did you want to
25 comment on that, and I am especially referring to that

1 discussion that you had with me on the Rambo mine.

2 MR. KUSEL: Yes. There was one issue where
3 in Australia there was a mine called Rumble, and that
4 is maybe 15 years ago, where a belt fire occurred, and
5 the belt was burned, and there was an issue between
6 the manufacturer and the authorities, the Australian
7 authorities, about the fire resistance of the belt.

8 And so as far as I know the manufacturer
9 said that the belt was approved, and it was okay when
10 it was supplied, and when it was tested. But after a
11 couple of years when the belt fire occurred, the belt
12 properties had changed.

13 So it was finally not solved, and I think
14 the main reason for Australia to come to more severe
15 requirements.

16 DR. BRUNE: Would those requirements include
17 testing at a later time, or let's say a validity date
18 until this belt can be used, almost like an expiration
19 date? Is that what the Australians do?

20 MR. KUSEL: I think the main point was that
21 the belt supplied was based on SBR rubber, and as we
22 heard yesterday, you have to add fire retardants to
23 get the flame resistant properties of the belt, which
24 is not the case in the neoprene.

25 So the Australian standards became more

1 stringent in this regard so that as of the new
2 regulations, only neoprene belts, which could not
3 deteriorate, would be approved and allowed.

4 DR. BRUNE: Thank you.

5 DR. WEEKS: I have a question about that.
6 You mentioned belts deteriorating over a period of
7 time. How much time are we talking about?

8 MR. KUSEL: Maybe 3 to 5 years. I am not
9 sure.

10 DR. WEEKS: Well, short in the life span of
11 the belt then.

12 MR. NORMANTON: Let me clarify that point.

13 MS. ZEILER: Could you wait one second so we
14 can give you the wireless microphone so everyone is on
15 the record. Thanks.

16 (Pause.)

17 MR. NORMANTON: My understanding of that was
18 different with an SBR belt, and that the fire was of
19 sufficient magnitude to cause propagation, and so I
20 don't think it was an issue of material, per se, but
21 that the composition of it in a worn condition was
22 different than as to when it was new. And under most
23 regulations worldwide, we are required to supply belts
24 that meet the regulation when new.

25 And often there are simulation tests to

1 predict the behavior when worn, as per some of the
2 U.K. tests, and Australian tests, where the curlers
3 are buffed away down to the fabric or down to the
4 steel cords.

5 And as manufacturers, those of us who would
6 test the products after being in the field for several
7 years, and we have a very thorough understanding if
8 there is going to be any changes in the performance of
9 fire resistance.

10 And I can't speak for other manufacturers,
11 but certainly ourselves, we don't feel that is a big
12 issue, or an issue at all.

13 In fact, the propagation test also requires
14 a strip of rubber being removed down to the fabric
15 also, and a hole punched through the belt to simulate
16 kind of a worn condition.

17 So that is a requirement that is found
18 around the world, but isn't currently a requirement in
19 the MSHA 30 CFR 18.65. It is kind of a subjective
20 area though as to what is a worn product.

21 DR. WEEKS: When you say that requirement is
22 found around the globe, can you say some more about
23 that and how does that show up in belts?

24 MR. NORMANTON: Some of the standards
25 require worn simulation testing in either the small

1 scale test or the large scale test.

2 DR. WEEKS: In minimal approval?

3 MR. NORMANTON: Yes, and also the ongoing
4 quality control.

5 DR. WEEKS: And it has to pass that test in
6 order to be approved?

7 MR. NORMANTON: Yes.

8 DR. WEEKS: Is there any time implications
9 involved?

10 MR. NORMANTON: No.

11 DR. WEEKS: Like a belt does not expire or
12 there is --

13 MR. NORMANTON: There is no expiration. I
14 mean, belt life can be one month, three years, 15
15 years, depending on the length of the products, and
16 the quality of the product also.

17 DR. MUTMANSKY: It just sort of came into my
18 mind that we have one more person who is likely to be
19 speaking on belt issues, and that person is Tom
20 McNider, who I believe will be speaking to us this
21 afternoon.

22 So that is another reason why the panel
23 should perhaps begin to discuss these things tomorrow
24 morning. Tom, you will be speaking on some of these
25 issues this afternoon I take it?

1 MR. MCNIDER: Yes.

2 DR. MUTMANSKY: Okay. So at this point is
3 there any other speakers who would like to discuss
4 these belt flammability issues, and in particular the
5 manufacturers who are here this morning, and may not
6 be here tomorrow morning? Are there any other
7 comments that you would like to make at this point in
8 time?

9 (No response.)

10 MS. ZEILER: If not right now, and they will
11 be here this afternoon, and they will still have an
12 opportunity in the public input hour. So we don't
13 need to close the door just yet.

14 DR. MUTMANSKY: Thank you, Linda.

15 MS. ZEILER: If there is no further
16 discussion, then we can take a break for lunch and
17 reconvene at 1:00.

18 (Whereupon, at 11:40 a.m., a luncheon recess
19 was taken.)

25 //

1 longwall panel extraction, and I will summarize the
2 results.

3 In the United States, there are
4 approximately 45 longwalls operating in coal. A lot
5 of totals end up using the two mines in Wyoming mining
6 and Trona, which should not be counted.

7 There are currently five entries, five mines
8 that use four entry gate road development system, and
9 39 of them that use a three entry system, and five
10 mines in Utah that use a two entry gate road system.

11 General guidelines taken from various
12 sources about air flow velocities that should be
13 expected in intakes and returns. For intakes and
14 returns, 600 to a thousand feet, dust starts becoming
15 an issue at the upper values.

16 The track entry, four to six hundred can be
17 higher, and if the belt is on intake, about a hundred
18 to 250, and when the belt is up by neutral, 50 up to
19 200 feet per minute out by.

20 MR. MUCHO: If I could interrupt you,
21 Robert.

22 MR. KROG: Please go ahead.

23 MR. MUCHO: Air velocity guidelines, where
24 are these guidelines coming from?

25 MR. KROG: Well, these are not strict

1 guidelines. They are not MSHA requirements. It has a
2 lot to do with economical based on how much -- you
3 know, at one point -- well, let me start back up
4 again.

5 The values have a lot to do with dust, and
6 once you get above 800 feet or so, you can start
7 picking up dust. The other part becomes what I refer
8 to as economical step functions to the right, and that
9 is putting more and more air through a single entry at
10 some point gets prohibitively expensive.

11 And then you would go to two and three, and
12 the same way you develop your mains. The number of
13 mains are developed by how much air you require, and
14 that determines how many mains you require.

15 When you are talking about gate road development,
16 you are trying to minimize the amount of gate road
17 entries you can have to get to your values. These
18 aren't strict numbers. The value -- and I believe it
19 was in 1984 in Mutmanský, was 1,150 feet per minute
20 maximum for a return.

21 That does not mean that you can apply that
22 to every single mine. These are just general type
23 guidelines. Does that answer your question, or --

24 MR. MUCHO: And the economics ties in where?

25 MR. KROG: Oh, the economics, and what I

1 refer to as an economic step function, a lot of times
2 people refer to an entry, and they just keep putting
3 more and more air into it, and they show that the
4 costs -- as you know, if you put twice as much air
5 through an entry, you get four times the head loss,
6 and it costs you eight times the requirement power.

7 But at some point, when I refer to economics
8 steps in, and where it becomes a step function, is
9 where it becomes beneficial to have two entries in
10 parallel instead of just putting all the air through
11 one entry.

12 So that is where it is an economic step
13 function. At some point, you keep moving more air,
14 but the economics is where you have to go to multiple
15 entries to supply your air or return your air, and
16 that is when you get a large -- I refer to it as an
17 economic step function on a per cost basis, including
18 capital.

19 DR. GALIZAYA: I have another question on
20 the same issue. What is it for the longwall face?

21 MR. KROG: For the longwall face, it is
22 about 600 feet per minute across the longwall face.

23 DR. GALIZAYA: Is that a guideline?

24 MR. KROG: No, I am not giving you a
25 guideline of what is required. I mean, that is based

1 on or is site specific. I am not giving you a
2 guideline to say what air is required on a longwall
3 face.

4 That is a combination of your methane, and
5 if you drained it, and what is your coal extraction
6 rate, and the height of your entry. For example, the
7 amount of air that gets moved in a Pokey Three mine,
8 compared to a Pittsburgh mine, that velocity isn't --
9 -- you can't just generally apply it to different coal
10 beds.

11 That's a function of an in situ mine.
12 That's why I didn't give a value of what is required
13 for a longwall. Does that answer your question?

14 DR. GALIZAYA: Yes.

15 MR. MUCHO: Let me just jump in.

16 MR. KROG: Go right ahead.

17 MR. MUCHO: Some of these numbers, like belt
18 intake, you have a hundred to 250 feet per minute.
19 That is with the belt on intake air, and I am still
20 having big problems with the word guidelines, I guess,
21 and where that is coming from.

22 MR. KROG: Let me say that these are not
23 NIOSH guidelines. I guess that is the key word.
24 Suggested is the better word, or what some mines are
25 doing in practice.

1 These are not guidelines that are rigid
2 requirements. These aren't legislative values. These
3 are just typically what mines that I have talked to
4 are dealing with, and how they are moving their air.

5 Like on the outby neutral, they are trying
6 to use the minimum requirement, which is 50 feet per
7 minute, but they require a little bit more than that
8 to get rid of the dust and the methane, and so they
9 put in a hundred feet per minute or 150 feet per
10 minute. These are more like ranges.

11 MR. MUCHO: So this would then be ranges of
12 what in general --

13 MR. KROG: Typical ranges. I think the term
14 would be typical air velocity ranges I think would be
15 a better description than guidelines.

16 MR. MUCHO: All right.

17 MR. KROG: The use of belt air, and
18 providing a secondary source of intake air to the
19 working face. A lot of previous work on using belt
20 air dealt with dust in like '96 and so, and dealt with
21 the amount of dust concentration that would be picked
22 up from a belt, compared to the amount of dust that
23 you get on the intake, and you get this simplified
24 equation, which is your concentration at the face, as
25 a combination of the concentration of the intake,

1 times the quantity, plus the concentration of the belt
2 air, times its quantity, divided by the intake and the
3 belt combined.

4 It is just a general type question. So if
5 you have a high amount of dust in your belt, it can
6 get diluted by the amount on the intake, on the intake
7 site, as long as the intake dust quantity is lower.

8 DR. WEEKS: It is a weighted average?

9 MR. KROG: It is a weighted average. It is
10 a simplified weighted average equation. That is
11 typically what was used for a calculation on the
12 creating of dust, assuming two entry points. The next
13 two slides are going to be based off previous work to
14 deal with dust. NIOSH went to four mines and measured
15 -- do we have a laser pointer?

16 (Pause.)

17 MR. KROG: What we have here are four mines
18 that had on their belts an intake that recorded the
19 dust, and it calculated value. The blue values right
20 there for all four are what the calculated or that
21 were measured dust levels in the belts.

22 I'm sorry, to white is the belts, and the
23 blue is the intake, and the yellow is the calculated,
24 using the previous equation on the previous slide, to
25 calculate what the expected dust load would be at the

1 face.

2 As you see the recorded dust loads were
3 significantly higher and the reason for this is that
4 the sample locations for the intake and the belt dust
5 air locations were out by the feeder breaker, and any
6 large source, continuous miners, and stuff, and so you
7 have a much higher reading in this case because a lot
8 of the dust creation sources are at the face.

9 MSHA at the same time did the same six mine
10 study, and they had similar type results, meaning that
11 the calculated values that they calculated that they
12 should have at the face were a lot less than the
13 actual recordings at the face.

14 And in two of these mines, you had a problem
15 when in this case the belt entry intake was actually
16 measured at 1.2 milligrams per meters cubed. The
17 reason for that is the very low amount of air flow
18 being brought up the belt, and in this case, about
19 4,000 CFM.

20 In mine six, they actually had another
21 problem when the belt air supplied more air to the
22 face than the intake, which is not allowed. NIOSH
23 about three years ago did a study dealing with
24 methane, and the calculation of methane components on
25 a longwall face.

1 What you have here is the calculated methane
2 at the tailgate, about 10 shields in from the
3 tailgate, and not actually dealing with the
4 interaction of the tailgate corner.

5 The shearer is the one in red, and that is
6 its component throughout the day, without this evening
7 shifting, and the green is the face conveyor or
8 armored face conveyor amount of methane, and the
9 component that came off of that.

10 What is of interest to the panel is the blue
11 one, which is the belts. This refers to about a 3,800
12 foot belt, with coal on it, that was used on intake,
13 and that is the component of the amount of gas that is
14 attributed to coming off the belts and being brought
15 to the headgate corner, and then being brought across
16 the longwall face.

17 What you have here is the calculated total
18 of all of them, and that one area is the back ground
19 base. Unlike the dust emissions, it does match up a
20 lot tighter because we are able to catch all of the
21 sources of methane on a longwall face.

22 But we ended up -- and one of the
23 conclusions that we had -- is that if you look at the
24 belt, which is the blue, it represented about 17 to 18
25 percent of the total methane on the longwall face that

1 actually came off the belt. That was our primary
2 conclusion from that study.

3 The effects of contaminations on face
4 concentration. The dust industrial readings are
5 greater at the face than what was calculated for the
6 simple fact that the places for the sampling location
7 is (sic) out by a lot of the major sources of dust,
8 and in this case, the feeder breaker is the biggest
9 one.

10 Gases, unless there is a gas inundation, or
11 an intrusion, or a large thing, or interaction with
12 the gob, the actual face concentration should be very
13 close to the calculated case, which bore out in the
14 slide previous.

15 CO and CO2, again, the value should match
16 what the calculated based on your intakes, assuming
17 that there isn't DO source or any major concentration
18 of CO or CO2 that is generated, i.e., something that
19 is in by the sampling locations.

20 DR. WEEKS: Did you take samples in by the
21 feeder breaker?

22 MR. KROG: I did not. The face -- going
23 back, in these cases here, these values were all taken
24 out by the feeder breaker, and those are actual face
25 recording measurements. So that incorporates the

1 feeder breaker. We didn't actually determine what the
2 feeder breaker was.

3 DR. WEEKS: Well, it is giving you a
4 mismatch, and your suggestion was because you had
5 placed the sample, and if you moved the sample.

6 MR. KROG: Yes, if you move the sample
7 location. I didn't actually do this. This is from
8 1996 data, and previous work with face with dust. But
9 previous work since then has looked at what is the
10 largest source of dust. Is it the feeder breaker and
11 such, and this is one of the results.

12 They just wanted to know -- it was just
13 looking at was the belt supplying a lot of the dust
14 towards the face, and that was the key requirement.
15 At that point, are you already going to fail by the
16 time that you get to the feeder breaker.

17 And it is to show that the readings that
18 they got were lower, the calculated were lower and
19 were a lot less natural, and so a lot of the dust was
20 actually created at the face.

21 Three entry gate road ventilation. That is
22 the most common layout in the United States, with
23 approximately 39, about 80 percent of the longwalls.
24 Belts on intake or neutral outby historically or
25 current.

1 The intake can be a track, or if there is no
2 track, a trout, which is usually the primary travel
3 way, and is also the primary escape way. This is a
4 generic three entry system from one mine that supplied
5 some data, but it applies to just generally all three
6 entry mines in the United States.

7 The bulk of the air still gets brought up
8 the track, which is a number two entry, and the number
9 one entry on belts in this case supplies 20,000 CFM,
10 and the track, 70, and the return is taking 90.

11 In this case the mine had 12,000 feet of
12 gateroad, with 65 crosscuts. I represented that this
13 one crosscut here represents about 61 of them, because
14 you can't actually do it to scale. It does not look
15 right.

16 So this is the summation of all the losses
17 throughout all of the stoppings between the number two
18 track and the number three return. They recorded
19 about 35,000 CFM leaking out, and had 55,000 CFM at
20 the last open crosscut.

21 Changing to -- well, let's just change the
22 belt to outby neutral, in which case they wanted to
23 dump 10,000 CFM at the start of it, and they figured
24 that they would have gotten 10,000 leakage through the
25 stoppings since now the belt is on a negative.

1 The same amount of -- this is assuming that
2 your main ventilation system can supply the same
3 90,000 CFM at the same pressure gradient across your
4 stoppings.

5 You get 90,000 being brought up your track,
6 and 70,000 being brought up your return, and you get a
7 reduction down to 30,000 of leakage, but the big
8 numbers here is the last open crosscut reduced from 55
9 down to 40.

10 And at this mine, this was not acceptable
11 for them during gateroad developments, and so they
12 decided to add some more air. Well, in doing that,
13 you would think that if you just needed to add another
14 15,000 to the last open crosscut, and so if you bring
15 20,000 up the track, you would be okay.

16 Well, that is actually not the case. Even
17 though you are bringing up 110,000 up the track, you
18 are not going to get the 55 at the front. The reason
19 why is the amount of air that you are bringing up the
20 track is going to increase your static loss down the
21 track.

22 The intake air flow is increased down the
23 track from 70 to 110,000. The pressure is RQ^2 ,
24 and the R stays the same. So you are looking at 2-1/2
25 times the pressure loss of bringing the air up the

1 track.

2 The next line here is the increased pressure
3 across the return stoppings, and so just looking
4 between two and three, the return is handling the same
5 amount of air, and relatively these are all general
6 statements, and these are just relative to the norm,
7 which is the base case, and we call that one.

8 You are going to have 2-1/2 times the
9 pressure loss down your track, and the same pressure
10 loss down the return. So you would expect to see
11 about 73 percent higher pressure across every stopping
12 up the belt, or I'm sorry, not the belt, but up the
13 track, number two track, and the number three return.

14 Quantity is PR square rooted, which because
15 you would have 73 percent more pressure, you expect to
16 see 32 percent more leakage across the stoppings.
17 Your stoppings were at 35,000 and they are now going
18 to increase to 46,000.

19 So that is another 11,000 CFM that you have
20 to bring down the track. The problem with that is
21 that you have increased the pressure again, and now
22 you can also leak into the belt.

23 The end result when you iterate this or
24 solve is that you come up with 130,000 CFM that is
25 required to bring up the track, and 10,000 is dumped

1 into the belts and outby neural, and you get about
2 15,000 leakage into your belt, and 50,000 leakage into
3 your return, and that is just to maintain the same
4 55,000 CFM at the last open crosscut.

5 So in summary, when you look at it, the belt
6 entry used to supply 20, and now it is exhausting 10
7 the feeder breaker, but actually when it is at the
8 recovery room, it is up to 25,000 because of the extra
9 15,000 leakage.

10 The intake is increased at the recovery room
11 from 70 to 130,000 and the return is also increased by
12 15. Leakage in the system went from 35 up to 65, and
13 you can also add the 10,000 that you are dumping into
14 the belt as well.

15 The requirement for this is -- and the big
16 thing about the changing of the belt in this case, is
17 that the mine had to supply from the main -- if you
18 are looking from the sub-mains to the gateroad, to
19 supply 40 percent more air and at over twice the
20 pressure across their stoppings to generate the same
21 55,000 at the last open crosscut.

22 Looking at the intake air velocities,
23 assuming it is a 15-1/2 foot entry by seven feet high
24 extraction, you get about 108-1/2 square feet. So
25 when the belt is on intake, and in the previous case,

1 and when it was bringing up 70,000, you would expect
2 about 650 feet per minute.

3 Under the final case, when it was bringing
4 130,000 CFM up the track entry, velocity is increased
5 to approximately 1,200 feet per minute, and that is at
6 the -- well, it is at the beginning of the panel,
7 because you get leakage. It is not 130 when it
8 actually reaches near the active face.

9 But if you consider the man trip ends up
10 blocking 25 percent of the cross-sectional area, then
11 that air velocity intake around the man trip can get
12 up to 1,600 feet per minute.

13 Three entry longwall extraction in eastern
14 mines, and here is a big thing, is that you can't take
15 a thing and apply it to all 49 active coal mines in
16 the United States that use longwalls, because each
17 coal bed has its own unique features.

18 This is referring to eastern mines, i.e.,
19 Northern Appalachian and Central Appalachian Basin.
20 Belt air methane liberation is a significant
21 contributor to longwall face methane readings. In the
22 previous -- about 10 slides before, the belt
23 represented about 17 to 19 percent of the methane
24 recorded near the tailgate corner of a longwall.

25 The use of intake belt air becomes a

1 hindrance as the longwall panels length increase,
2 i.e., you go from 10,000 to 14,000, to 15,000 feet in
3 length, because you have that much more belt and that
4 much more time for the coal in the belt to de-gas on
5 its way out of the mine if you are going to bring that
6 air to your face.

7 An example of one mine, and I will go to the
8 slide here, they had a 14,000 foot long panel, and
9 they started it up, and within a few hundred feet of
10 startup, when they are starting up the full
11 production, they started getting gassed out on the
12 longwall face.

13 And the reason for it is they were recording
14 .7 percent methane coming up the belt. They were
15 bringing 25,000 CFM up their belt, and they were
16 getting loaded to about .7 percent on that, and that
17 to them was unacceptable and they needed to change.

18 Since they were so close to the bleeder
19 system, they knew that their exhaust system could
20 handle getting rid of large quantities of air, but
21 they just had difficulty supplying it down the 14,000
22 feet of gate road.

23 What they ended up doing was converting the
24 number three return to an intake, and taking the belts
25 on outby neutral. They noticed a lot of advantages by

1 doing this. One, they were able to supply a lot more
2 air to the headgate, and increased air flow along the
3 longwall.

4 This is to show the before, and this is when
5 it was on intake, and this is when the belt was on
6 return. The same 25,000 was being brought up to the
7 face, and then 25,000 was being brought out.

8 The intakes stayed the same at 80,000 CFM.
9 The return went from exhausting 30,000 to bringing in
10 50,000. The air flow at the number 10 shield on the
11 longwall face went from 55 to 80,000 CFM, and at
12 shield 139, which was about 10 shields in from the end
13 of their panel, it went from 75 to 60. So they
14 increased the air flow along the longwall panel quite
15 significantly.

16 The key thing to look at is how much air was
17 supplied to the headgate T-junction. In the previous
18 system, they were able to bring 75,000 CFM up. Now
19 they are able to bring 105,000 CFM up, which is a 40
20 percent increase.

21 The advantages for them changing over in
22 this particular mine, and changing over to using belt
23 outby, is the belt is on outby. They have a secondary
24 isolated intake, and I should note that to do this
25 that they had to go back and reinstall about six

1 overcasts to allow them to change over their
2 ventilation system.

3 They had a second isolated intake, and so
4 they have a primary and secondary, and so their
5 primary is their track, and their secondary intake was
6 their number three, and that was now an intake.

7 Because there (sic) is two parallel
8 intakes, the headgate corner is now at a relatively
9 higher pressure than it was before, because the belt
10 on that is only moving 25,000 out. So really you are
11 not pressurizing it. I don't want to use that term,
12 but it is still negative pressure because the line is
13 on return.

14 But you have a higher relative pressure at
15 the headgate corner, which allows multiple things.
16 You can increase your air flow quantity across the
17 face, assuming that your bleeder system or main return
18 air system can still get rid of the air.

19 But the biggest thing during daylight is
20 that they had an increased amount of air at their
21 headgate corner, and they were able to increase the
22 amount of air that they were able to dump into the
23 bleeders as a sweetener.

24 The reason for this is as you know panels
25 are getting longer, and wider, and there is more and

1 more gob air. And you are taxing the bleeder system
2 and you are removing more and more of the methane. So
3 to allow that to happen, you still have to add
4 sweetener to the bleeder system, and the best part to
5 do that is actually on the active longwall panel.

6 So to summarize, eastern mines, three entry
7 gateroads in general have a difficult time during
8 development with the belt on outby neutral without
9 using pre-methane drainage or even extensive pre-
10 methane drainage.

11 The case that I showed that had 130,000 CFM
12 coming up the track, to them when they say it is
13 economic and everything is interconnected, they are
14 under the belief now that they if they could do even
15 more and more methane drainage that they can reduce
16 that number, because they won't require as much air at
17 the face if they can reduce the amount of in situ
18 methane in the coal.

19 Three gateroads during panel extraction have
20 over the past, and this is in the eastern coal mines,
21 have over the past few years almost gone to
22 exclusively using dual intakes with the intake on
23 outby neutral.

24 Western mines and Illinois mines are a
25 little different. In fact, western mines, if you use

1 the Utah mines, five of them being on two entry
2 gateroads, the belt air is required to be on intake
3 during longwall extraction.

4 They also have the problem with spontaneous
5 combustion of the coals out there, which changes the
6 generalized practice as it is applied to eastern
7 mines.

8 The Illinois Basin also has a different
9 case, because their coal, unlike coals in the east,
10 don't de-gas as much on the belt outby. So for them
11 using the same 14,000 foot belt, they are not going to
12 get -- generally they are not going to get as much gas
13 coming off their coal, thereby increasing the methane
14 load coming towards the longwall face corner. So the
15 belt air does not bring excessive methane to the
16 working areas, and questions?

17 DR. TIEN: Robert, that is quite
18 interesting. I just have a general question. Do you
19 by any chance have data, pressure drop data, for the
20 14,000 feet longwood panel?

21 MR. KROG: I do not on me, no.

22 DR. TIEN: How about a cross-face?

23 MR. KROG: Pardon?

24 DR. TIEN: Across the longwall panel face?
25 Do you have pressure drop data on that?

1 MR. KROG: No, we didn't take that pressure
2 reading data.

3 DR. TIEN: Now you covered the longwall
4 setup pretty well. Did you have any chance to work on
5 the continuous mining section panels?

6 MR. KROG: No, I was told to just deal with
7 using belt air on longwall faces. I didn't deal with,
8 or to get data on all the -- are you referring to room
9 and pillar sections that use belts?

10 DR. TIEN: I am talking about the panel and
11 using the continuous mining method?

12 DR. BRUNE: Development sections.

13 DR. TIEN: Development sections, yeah. Have
14 you had a chance to use the belt air, either a
15 blowing system or ventilation system, or return
16 system?

17 MR. KROG: Are you talking mains, sub-mains,
18 or --

19 DR. TIEN: No, just the panel, the long
20 panel.

21 MR. MUCHO: Driveage.

22 MR. KROG: Oh, okay. No, we did not get
23 into that. I'm sorry. I didn't cover that section.

24 DR. TIEN: It might be helpful because we
25 are still talking about 50 or 45 percent using

1 continuous mining methods.

2 MR. KROG: Yes.

3 DR. BRUNE: Robert, just one question about
4 definitions. Is outby neutral identical to belt on
5 return?

6 MR. KROG: Belt on return, yes.

7 DR. BRUNE: Is that the same? I think we
8 need to make that clear. The other question I picked
9 up is that you mentioned that in western mines that
10 have two entry development during longwall extraction,
11 belt air is required to be on intake; is that correct?

12 MR. KROG: I'm sorry, I did not mean
13 required. Belt air is used on intake so they can
14 supply enough air.

15 DR. BRUNE: Right, it is typically used. It
16 is not a requirement.

17 MR. KROG: It is not a requirement.

18 DR. BRUNE: I just wanted to clarify that.

19 MR. KROG: If you worried about getting
20 gassed out, it is typically that those mines use belts
21 on --

22 DR. BRUNE: I understand that they typically
23 do, but I was just tripping over the requirement.

24 MR. KROG: Sorry for my incorrect use of the
25 word.

1 MR. MUCHO: I would like to debate, Robert,
2 the statement as far as the generalities that the use
3 of intake air becomes a hinderance as the longwall
4 panel increases in length.

5 MR. KROG: Based on which coal you are
6 using.

7 MR. MUCHO: Generally, for the reasons that
8 you have given, that's true, but you are assuming
9 there that -- for instance, I am bringing the belt air
10 in outby the mouth of the panel, or at the mouth the
11 panel, and so it is traveling over the length of the
12 belt.

13 So as I increase the length of the belt, I
14 increase the gas and so on, and so forth. Really, it
15 comes down to the quantities as you showed in the one
16 equation.

17 MR. KROG: Yes.

18 MR. MUCHO: And the concentration of the
19 contaminant, and the quantities of the belt air, and
20 the contaminant of the other intake lines to make the
21 face air, and its contaminant and quantity.

22 So let's say for longer panels, ventilation
23 schemes such as if I would point feed midway up the
24 panel, where I am now bringing back quantity in only
25 on half of the length of the belt, and maybe bringing

1 in a very large quantity at that point, a large
2 quantity having a bearing on pollution effect, et
3 cetera, on face air, then I get a different answer
4 from that ventilation scheme from the generalized
5 statement that we have here.

6 MR. KROG: The generalized statement is
7 assuming the entire length of the belt is being
8 brought up to the face. If you are going to mid-panel
9 or a thousand feet in front of it, and dumping that,
10 you completely change the methane equation.

11 MR. MUCHO: I understood that is not fully
12 applicable as a generalization in all cases, on the
13 depending on the ventilation system?

14 MR. KROG: The case that I showed, that .7
15 percent, that is a case where you are dumping 3,000
16 tons per hour on to a belt, and pulling that belt out
17 in the same 25,000.

18 So the air flow is only moving about almost
19 300 feet per minute, and so there is not a lot of air
20 moving up the belt. So, yes, that is a big change in
21 the amount, and also the coal was de-gassing that
22 whole length at the time.

23 DR. GALIZAYA: I have another question.
24 Again, a general question. When you talk about
25 western mines using a three entry system, could you

1 elaborate a little bit more on the reasons for some of
2 those mines using that system?

3 MR. KROG: I was under the assumption that
4 the two -- it was about 1984 when Cottonwood Mine
5 fought -- no, not fought, but took legal action to
6 allow them to go to a two entry gateroad system was
7 based off of the reduction of bumps out in Utah, which
8 was very deep mines.

9 And you physically can't have a three entry
10 system and keep the middle entry open under a yield
11 pillar design with a two gate road. What I am
12 referring to is the two entry longwall here. This is
13 a yielding type pillar, which doesn't leave the stress
14 abutment, which doesn't allow the huge bumps to occur
15 in the mines.

16 So they are limited to having two entries.
17 They also have or they can have some higher heights
18 than required here so that they can bring -- so that
19 the two entries have enough air quantities to allow
20 them to mine.

21 But under my assumption, the two entry is
22 primarily a result of ground control issues not
23 allowing a three entry system. So the Utah mines,
24 that was a court settlement that came out in '84 to
25 '86.

1 MS. ZEILER: Okay. Thank you very much,
2 Robert. Our last NIOSH presentation for this meeting
3 will be from Fred Kissell, who will speak to us on
4 mine escape issues.

5 (Pause.)

6 DR. KISSELL: For the record, my name is
7 Fred Kissell, and I am one of those recycled retirees
8 from NIOSH, brought back to discuss research that took
9 place 15 to 20 years ago, and fortunately I have some
10 memory of what happened and so I would like to impart
11 that with you today.

12 My task is to talk about four research
13 studies that were conducted, and of those four, the
14 first was to pressurize intake escape ways -- you can
15 see the lead slide -- to reduce the infiltration of
16 smoke.

17 The second study dealt with what are the
18 major hindrances to escape from mine fires, and I had
19 some pretty stunning results I thought with regard to
20 the impact of smoke, versus the impact of other
21 factors.

22 That is the first two. The last two studies
23 were a fault tree study, and a systems analysis study,
24 where we attempted to get our arms around the problem
25 of escape as a whole. In other words, basically to

1 recognize that there are many factors impacting
2 escape, and whether you get out of a mine depends on
3 literally dozens of factors.

4 So the question is which of these factors
5 are more important and which are less important,
6 because that is really crucial if we are to improve
7 the probability that miners are going to escape during
8 a fire.

9 So, anyway, having said that, I would like
10 to deal with the first study. I am told that this
11 lower right-hand button is the one to push. The
12 original idea to pressurize intake escape ways to
13 reduce infiltration of smoke came from Don Mitchell,
14 and it was in the book, Mine Fires.

15 And he suggested in the book that if you
16 checked off the intake escapeway, you might raise the
17 intake escapeway pressure and reduce infiltration of
18 smoke.

19 And we had invented the parachute stopping
20 years earlier, back in the early '70s, as a way of --
21 for a temporary check curtain that found its way in
22 uranium mines when uranium mines were still in
23 business.

24 And we speculated that a parachute stopping
25 would work well as a temporary check curtain. It goes

1 up in just a few minutes, and leaks less than a
2 regular check curtain. So the question is could you
3 use that to check off an intake escapeway, and if you
4 raised the pressure of the intake escapeway, how much
5 would it go up, and would it really work.

6 So that is really what the project was all
7 about. This was done by Bob Timko and I, and
8 published in '91. A typical layout. We visited six
9 mines, and in those six mines, we conducted 10 tests
10 in different sections.

11 A typical layout was this in line B. This
12 was a four entry development. The panel belt was on
13 return, and for the test, what we did is with the
14 parachute down, first of all, what we would do is we
15 walk out by and measure the pressure at each door
16 between the intake and the adjacent entries, and just
17 throwing a tube through the door and measuring the
18 pressure with Magnehelic.

19 And we would walk out by as far as we
20 possibly could to either the mains or sub-mains,
21 several thousand feet. And then what we would do is
22 we would throw up the parachute, which just took a
23 minute or two.

24 And then we would go back and remeasure all
25 of those door pressures between the intake escapeway

1 and the adjacent airways to find out how much the
2 pressure went up, and was it considerable, and we
3 would walk out by it to find out how far the effect
4 lasted as well.

5 So these were our results, and this is
6 typical. They were all about the same. Basically you
7 could see with the parachute down, we measured the
8 pressure between the intake, and the escapeway, and
9 the belt, and you could see basically the intake
10 escapeway was higher pressure than the belt. It was
11 about the same as the track.

12 We threw the parachute up, and typically you
13 would get an increase in pressure of about a tenth of
14 an inch water gauge. Here again the pressure between
15 the intake escapeway and the belt, and here the intake
16 escapeway in the track.

17 Interestingly enough the results for all of
18 the mines and all of the tests were roughly similar,
19 and we basically got a tenth of an inch water gauge
20 improvement.

21 It is also interesting to note, and I don't
22 have really a slide for that, but what happens is that
23 in eight out of the ten tests the pressure in the
24 intake escapeway was already higher than the pressure
25 in the belt, whether or not the belt was on intake or

1 return.

2 It was a little higher and so the belt was
3 on return, but in general the intake escapeway was at
4 a higher pressure than the belt, which kind of
5 surprised us, but that is the way that it turned out.

6 DR. MUTMANSKY: Fred, a comment. Because of
7 the direction of the air as shown, go back to the
8 slide where it showed the mine layout. You see the
9 intake air is coming up into the section, and the belt
10 is coming back from the section. It is always going
11 to be a positive pressure difference between the
12 intake and the belt on that section.

13 DR. KISSELL: On that section, right.

14 DR. MUTMANSKY: Whereas, if you reverse the
15 belt, that will be where you have the problematical
16 situation. Did you look at it under those conditions?

17 DR. KISSELL: Oh, sure. In most instances,
18 in most of the tests, the belt was on intake and not
19 on return. For most of the tests the best was on
20 intake and the intake escapeway pressure was still
21 higher than the belt.

22 DR. MUTMANSKY: Okay. Good.

23 DR. KISSELL: I really have no explanation
24 for that other than the fact that the belt structure
25 itself has a real big impact. But the fact of the

1 matter is that the intake escapeway pressure was
2 higher than the belt in eight out of the ten times.
3 Now, not by much. Just by a couple of pascals, but it
4 was higher.

5 DR. TIEN: Fred, on the previous slide, you
6 have covered -- oh, this was the vertical or the
7 distance. Okay.

8 DR. KISSELL: Thanks for mentioning that. I
9 forgot to mention that essentially this effect, this
10 inch of water gauge that you buy by erecting the
11 parachute diminished as you went outby, but in general
12 there was some effect up to about 4,000 feet outby.

13 DR. TIEN: And also did you have a chance to
14 characterize the leakage before and after the test?
15 The leakage of the stoppings.

16 DR. KISSELL: No. We measured section air
17 flow in addition to measuring pressure through the
18 doors. Interestingly, the escapeway air flow fell by
19 70 percent. In other words, the leakage past the
20 parachute was 21 percent.

21 But when we measured the face air flow, it
22 only fell by six percent. So obviously what was
23 happening was that air coming down the intake
24 escapeway was being rerouted to the other airways, and
25 then still going to the face nevertheless. That is

1 what was happening.

2 So essentially we weren't really reducing
3 much of the air flow that went to the face, but we
4 were rerouting it into adjacent airways, and that sort
5 of makes sense looking at it and considering how leaky
6 mine stoppings are.

7 MR. MUCHO: By that you mean leaking
8 basically?

9 DR. KISSELL: Yes, and that sort of speaks
10 to its ability to keep out smoke as well, because
11 clearly if you are leaking into a belt, you are not
12 going to have smoke moving in the other direction.

13 The conclusions from that study were
14 parachute stoppings helped to keep smoke out of the
15 escapeway if the fire source is not in the escapeway.
16 Now, that is a big if, and it will depend on the mine,
17 and it will depend on the number of entries.

18 But basically that was our conclusion, that
19 the entry water gauge was pretty considerable compared
20 to the existing pressures, and it would actually work
21 quite well to keep smoke out of the escapeway if the
22 fire source was not in the escapeway. The next study
23 --

24 DR. BRUNE: May I ask a question before you
25 go to the next study?

1 DR. KISSELL: Yes.

2 DR. BRUNE: Fred, what would be the impact
3 of putting up the parachute, the impact on the overall
4 mine ventilation system? I am thinking in case of a
5 fire, the last thing that you want to do is change or
6 make significant changes to the mine ventilation
7 system.

8 And that would be a concern to me as a mine
9 operator to put up a parachute and possibly change or
10 reverse the air that travels over the fire.

11 DR. KISSELL: I don't think there was much
12 of a change at all. We may have made some
13 measurements back in the mains and the sub-mains, and
14 didn't see any difference. Frankly the amount of air
15 reaching the face didn't change.

16 And if it did, I would have said maybe there
17 is an impact on the mine ventilation system, but since
18 the amount of air reaching the face only changed by
19 six percent, that is a pretty small change.

20 And all it did was reroute the air into
21 adjacent airways. So my guess -- and Rob might
22 remember whether we took any measurements in the
23 mains. Did we?

24 MR. TIMKO: No.

25 DR. KISSELL: We didn't? Okay. My guess is

1 that there is not much of a change frankly.

2 MR. MUCHO: Fred, before you move on, I
3 would like to stay with this one. I will ask the same
4 question that I asked in Washington of someone else,
5 and about the same talk.

6 This was brought up before the 1992 advisory
7 committee, and the 1992 advisory committee recommended
8 that this type of approach be used for e-ability, et
9 cetera, and then it sort of disappeared from the face
10 of the earth until here we go again today with it.

11 Do you know why that disappeared? Do you
12 have any feel for that, and why this has not caught on
13 as a concept for escape?

14 DR. KISSELL: Well, although it was an
15 interesting study and I think it worked well, I had
16 mixed feelings about itself. In general, I think it
17 is better to take action to prevent mine fires from
18 happening in the first place than it is to take after
19 the fact actions.

20 And I think back in the early '90s there were
21 more fire sources in escape airways than there are
22 now, because there is more -- well, you can't put, for
23 example, a compressor in an intake escapeway.

24 MR. MUCHO: Right.

25 DR. KISSELL: And so just the fact that

1 there were a lot of fire sources in the intake
2 escapeways at the time may have mitigated against
3 using this, because frankly if there is a fire source
4 in the intake escapeway, and you throw up a parachute
5 to block it, you are going to have -- you basically
6 are going to have more leakage into the adjacent
7 airways that you want to escape out of. So it would
8 create a serious problem.

9 MR. MUCHO: Right. Your previous slide, if
10 the fire is not in the escapeway, and of course the
11 assumption there is that the miners know where the
12 fire is located, and it is or is not in the intake
13 escapeway, and that would dictate their actions.

14 DR. KISSELL: Right.

15 MR. MUCHO: And with communications today,
16 that is the whole big thing, but --

17 DR. KISSELL: Traditionally, nobody has
18 known where the fire was anyway if you know what I
19 mean. I am thinking --

20 MR. MUCHO: It varies in some cases. I
21 mean, the '58 fire, they knew where it was at.

22 DR. KISSELL: Some people may know it, but
23 the people inby may not. Any more questions?

24 DR. TIEN: Can I make a general comment?
25 Usually we refer to leakage as being an undesirable

1 factor, or we try to reduce leakage, but in this
2 particular situation, leakage will actually help you
3 to redistribute the air.

4 DR. KISSELL: Well, yes and no. I mean, if
5 you had less leakage, your pressure difference between
6 the intake escapeway and the adjacent airways would be
7 even higher than an inch water gauge. So it is really
8 a mixed bag.

9 DR. TIEN: It depends on the situation, yes.

10 DR. KISSELL: Yes. It is really a mixed
11 bag. Anymore before we go on?

12 (No response.)

13 DR. KISSELL: The second study we did, and
14 this is a study that Dave Litton and I did, how smoker
15 hinders escape from coal mine fires, and this came
16 from perusing through some of their smoke optical
17 density, carbon monoxide measurements that I was doing
18 after they conducted one of their conveyor belt burns.

19 And what happened was that I ran across a
20 table that they published that gave carbon monoxide
21 values at various optical density values. This is
22 basically an optical density of a tenth of a meter, or
23 tenths per meter. The units and optical density are
24 reciprocal meters, and with the visibility of 26 feet.

25 And I looked at this table and a couple of

1 things struck me at the time, and we are talking about
2 back in 1990 or so. First of all, is that the CO
3 concentration for a given visibility level, for
4 approximate purposes, they are within fairly close
5 tolerances.

6 In fact, there is more difference between CO
7 flaming and CO smoldering. That was the first thing
8 that I noticed. A second thing I noticed is that for
9 visibility of 26 feet, the CO levels here are
10 remarkably low. They are just remarkably low.

11 And these work in a reciprocal manner. In
12 other words, basically if we can imagine that smoke is
13 four times as dense at four-tenths per meter, that
14 leads to a visibility of a fourth of that value, or
15 about 6-1/2 feet.

16 And essentially leads to, say, for an SBR
17 belt, a CO concentration of 15 parts per million. In
18 other words, the numbers were really, really eye-
19 opening for me, because essentially people were
20 running out of visibility at relatively low carbon
21 monoxide values.

22 And so the question here was, well, what
23 exactly is preventing people from getting out of
24 mines. Is it the carbon monoxide or is it the lack of
25 visibility.

1 And I decided to investigate this a little
2 bit further, and Dave Litton and I put a little
3 project together. These numbers basically on CO and
4 on optical density come from various meters that they
5 use, an optical density meter of some sort.

6 So what we did is we set up -- I think it
7 was an SBR belt burn in the Lake Lynn mine, with a
8 couple of square yards of conveyor belt, and we set up
9 a video camera downstream of the belt, and at 25 feet
10 from the video camera, we put a scarecrow of some
11 sort.

12 And then between 25 feet and the camera, we
13 put up wooden placards with numbers written on them,
14 and it is sort of a standard procedure that people use
15 for measuring optical density in fires.

16 So we also measured the carbon monoxide
17 concentration at the same time, and later when we
18 looked at the video tape from the camera, we could see
19 essentially the smoke getting thicker and thicker, and
20 eventually the scarecrow would disappear, and then the
21 various signs at various distances would disappear.

22 And so we could get a feel for what the
23 visibility was, and since we measured carbon monoxide
24 at the same time, we could get a feel for where the
25 carbon monoxide was. So essentially we got this. The

1 outer curve here, the longer one, is essentially from
2 their measurements of optical density and from the
3 measurement of carbon monoxide.

4 And our direct visual observations using a
5 video camera are the shorter curve right here. They
6 correlate reasonably well, but the stunning feature of
7 this frankly is the fact that at relatively small
8 visibilities -- and by the way, about 12 feet
9 visibility is the generally accepted minimum for
10 escape from building fires.

11 That is basically a number enshrined in
12 general escape. You need 12 feet to get out. But
13 underground 12 feet corresponds to roughly a
14 concentration level, a CO level of about 30 parts per
15 million.

16 Which means essentially that smoke is the
17 major factor preventing escape from mine fires, and
18 not carbon monoxide. Now people may die of carbon
19 monoxide. When there is an autopsy, there is carbon
20 monoxide in the blood.

21 But the main factor that prevents these
22 folks from getting into fresh air is the loss of
23 visibility and they get lost. That was really a very
24 surprising thing to us, and to examine it a little
25 further, we set up a little model, and essentially

1 established an entry with a fire over here, and that
2 fire produced contaminants of a concentration of C
3 Sabeth.

4 There is some stopping leakage into an
5 escapeway that has air flow QCB, with a leakage QCL,
6 and the contaminants in the escapeway are calculated
7 in a rather straightforward fashion using simple
8 proportions here.

9 So, anyway, using that model, and keep this
10 model in mind, because we will be referring to it in a
11 subsequent paper, too. But what I did now is plot
12 visibility versus leakage into the escapeway, and over
13 here we are plotting carbon monoxide and we are
14 actually plotting oxygen as well.

15 And you can see that there is some common
16 sense here. As the leakage goes up, the visibility
17 goes down, and the carbon monoxide goes up, and the
18 oxygen goes down. That is all that we are plotting
19 here.

20 Now, our visibility minimum of 12 feet I am
21 plotting right here, and our CO critical maximum, the
22 IDLH level, this is fifteen hundred parts per million
23 back in the early '90s, and I know that it is lower
24 now. These numbers keep going down.

25 But that was the number basically that was

1 relevant then. We can see from this curve
2 interestingly enough that as the leakage changes, we
3 have reached the visibility minimum at 200 CFM leakage
4 into the escapeway.

5 In other words, we run out of visibility at
6 200 CFM leakage, and as the leakage goes up, the CO
7 also goes up, but we never reach the CO critical
8 maximum even with 20,000 CFM leakage.

9 In other words, a leakage value of one
10 percent of 20,000, we have already run out of
11 visibility, and at 20,000 leakage, we haven't even
12 reached the CO critical maximum yet.

13 In other words, we run out of visibility at
14 values of leakage, a percent or less than the value
15 that it takes to do us in with carbon monoxide.

16 Now, on that basis, the paper recommended
17 the use of lifelines, and today we have lifelines,
18 probably one of the best things that could have
19 happened in a long time, and I think this paper also
20 led to the NIOSH recommendation a few years ago that
21 NIOSH or rather MSHA require directional lifelines.

22 So lifelines have had a tremendous impact, I
23 believe, in promoting mine safety, and improving
24 escape from mine fires.

25 Our conclusions? Of course, I mentioned

1 lack of visibility and smoke, and the accompanying
2 fumes are the greatest obstacles to safe escape. You
3 saw those black clouds coming out of the conveyor belt
4 burn at Lake Lynn, okay?

5 You would have been amazed at how low -- I
6 don't have any numbers here, but you would be
7 surprised at how low the carbon monoxide concentration
8 in those clouds was, a couple hundred parts per
9 million probably.

10 So it is lack of visibility that is really
11 the primary problem, and it is really good that we
12 have come around as a nation to dealing with that.
13 Any questions before I go on?

14 DR. WEEKS: What was the material that you
15 were burning to make this smoke?

16 DR. KISSELL: SBR belt. But it really
17 doesn't matter because essentially all the
18 concentrations for the various belts, and even coal,
19 they are all relatively about the same.

20 That is what surprised me. There is
21 generally for most of these burning materials that
22 will burn in mines, with the exception of wood, which
23 is a little different, a CO to smoke ratio, CO to
24 optical density ratio, and once you specify the CO,
25 you pretty much know the optical density and vice

1 versa. That's the interesting thing about it.

2 DR. BRUNE: And is it correct that you had
3 oxygen enriched burning conditions and not fuel rich?

4 DR. KISSELL: Yes, that's right, 21 percent
5 oxygen and whatever is normal. Yes, Jim?

6 DR. MUTMANSKY: I believe the human reaction
7 to CO though is cumulative; that is, regardless of
8 what level of CO you are at, you begin to accumulate
9 the problem in the hemoglobin of the blood, and it
10 gets worse over time. Did you take a look at that
11 particular effect?

12 DR. KISSELL: No. We are looking basically
13 at all short term effects, and whether you can see
14 this minute or can't, and that's why we used the IDLH
15 level rather than any kind of an SDL or long term
16 level.

17 It is probably in fact why the autopsies of
18 these fallen miners showed fairly high CO levels in
19 the blood, too, because they had been breathing it for
20 a long time.

21 MS. ZEILER: Jim, you have to move up to the
22 microphone, please.

23 DR. WEEKS: In a mine fire what would you
24 say is the nature of fuel status if you get smoke?
25 Would it be coal?

1 DR. KISSELL: I can't answer that. You
2 would have to turn to the fire guys to do that, and
3 essentially, the fires -- they have explained that the
4 fires that they have used or they have started, was
5 either a coal fire or a tray fire, and they burned
6 primarily the belt, but started a coal or tray fire.

7 The fire that we built at Lake Lynn started,
8 I believe, with strip heaters in a pile of coal, and
9 then went from there to burn the belt.

10 DR. WEEKS: The issue is whether it is
11 worthwhile to worry about the optical density of smoke
12 from the belt, and if we produce that would it make
13 any difference?

14 DR. KISSELL: I would have to take a look.
15 Here is coal versus SBR belt, and PVC belt, and
16 neoprene belt, and it is really all in the same range.

17 DR. WEEKS: I am assuming that something can
18 be done to the belt where there would be no smoke?

19 DR. KISSELL: Sure, if it didn't burn in the
20 first place, it wouldn't produce much smoke.

21 DR. WEEKS: Well, that's true, too, assuming
22 that it is going to burn and produce this smoke. But
23 it doesn't contribute much to the overall smoke, then
24 if you worry about reducing the amount of smoke on any
25 particular belt line, then -- well, if the smoke --

1 DR. KISSELL: I think you reduce the smoke
2 from belts the same way you reduce the toxic acids
3 from belts. You have a belt that doesn't burn in the
4 first place.

5 DR. WEEKS: Yes, but I am assuming that it
6 is going to burn for purposes of this issue.

7 DR. KISSELL: I can't answer that. I really
8 don't have any research to address that issue.

9 DR. WEEKS: Well, that is the issue, and is
10 it worthwhile worrying about the optimum density of
11 the smoke resulting from the belt burning.

12 DR. KISSELL: I don't know. The simple
13 answer would be basically if you can find a belt that
14 doesn't burn, it reduces the smoke and reduces the
15 toxic acids.

16 DR. WEEKS: You said that three times. We
17 are getting there.

18 DR. BRUNE: Based on your conclusion would
19 it be fair to say that an optical density or smoke
20 obscuration sensor is a better indicator of a fire
21 source than a CO sensor?

22 DR. KISSELL: You would have to talk to Dave
23 Litton about that.

24 DR. BRUNE: I am asking you.

25 DR. KISSELL: Yes, and I don't know. They

1 have done some research on smoke sensors, and I think
2 they find that a smoke sensor, yes, does in fact
3 detect a fire more (sic) earlier than a CO sensor,
4 yes.

5 But basically whether they got to the point
6 where they could say that these things were reasonably
7 reliable and didn't have a lot of false alarms, that
8 is a problem, because of so much dust in conveyor belt
9 lines, anything that depends on optical sensing is
10 really problematic. That is the difficulty. But
11 where that research stands, I don't know.

12 DR. BRUNE: Okay. We will talk to Mr.
13 Litton about it.

14 DR. KISSELL: Okay. The third study is
15 evaluating those factors that influence escape from
16 coal mine fires. This is a study that Gerrit Goodman
17 and I did back in the late '80s, and this study and
18 the next one are both essentially system studies in an
19 attempt to get our hands around what factors impact
20 escape, and what factors are more important or less
21 important.

22 And the first approach that we took was
23 essentially a fault tree approach, and I am sure that
24 all of you have heard of fault trees. They are used
25 extensively in the chemical, aerospace, and nuclear

1 industries, to analyze basically the probability of
2 failure.

3 And the strength of a fault tree is that you
4 can establish a top event, which is the failure of the
5 system, and then establish so-called starting events
6 that contribute to the failure, and given the
7 probability of starting events, you can calculate a
8 probability of failure.

9 And given changes in the probability of
10 starting events, you can essentially calculate the
11 overall probability of failure. And it struck us that
12 this might be a powerful technique to look at mine
13 fires, because we could say to ourselves, well, we can
14 establish a probability that the AMS system would
15 fail, and a probability that self-rescuers would fail,
16 and a probability that stoppings would leak more than
17 normal.

18 And so now the question is if we change
19 these probabilities by a fixed amount what is the
20 overall impact of these individual changes, okay?
21 Fault trees have not been used much in the mining
22 industry, and in this regard, we were sort of blazing
23 new ground.

24 But the results of this study, and I think
25 the next study, were pretty substantial in pointing us

1 into the proper directions. Here is an example of an
2 ultra-simple fault tree, and not the one that we used,
3 but it has only got a couple of levels.

4 Basically, we are hypothesizing in this tree
5 that there is a so-called failure to escape, a
6 probability associated with a failure to escape, and
7 through this logic tree, we can say that this results
8 either from being lost in smoke, or a failure in a
9 self-contained self-rescuer.

10 Now if we had probability values for lost in
11 smoke, and a probability value for SCSR fails.
12 Through the OR gate, we can calculate a failure to
13 escape probability.

14 Now, of course, whether the SCSR fails is
15 dependent on other factors, and so now we can work our
16 way down through the fault tree at various so-called
17 starting events and vary the probability of the
18 starting events to see what the probability of failure
19 to escape is.

20 Now the actual tree, I am not going to show
21 it to you. It had over 20 starting events, and about
22 20 levels, and it is really too much to fit on a small
23 slide here, but I think you get the general idea.

24 Let me give you some results from our fault
25 tree analysis. For example, we looked at top event

1 values for changes in SCSR training escapeway
2 knowledge. That is what this is. And these are the
3 top event values in this three-by-four matrix right
4 here.

5 And here we are plotting basically the
6 probability that there is going to be some error in
7 putting on and using, or functioning of the SCSR,
8 anywhere from a tenth to .93.

9 There is another probability of finding the
10 escapeway, and that you will get lost and never get in
11 the escapeway in the first place, and we varied that
12 from a tenth to nine-tenths.

13 And you can see basically -- well, first of
14 all, there is (sic) some common sense things here. If
15 you don't find the escapeway, it doesn't matter
16 whether you have much or any air in the SCSR.

17 Correspondingly, if you have a high error in
18 the SCSR, it is more than likely that this SCSR is
19 going to fail, then obviously if there is no change in
20 whether you get out, depending on whether you find the
21 escapeway or not.

22 But the other interesting thing here is that
23 when we see a high probability of finding the
24 escapeway, and a low SCSR error, we have essentially a
25 probability of failure and not getting out at .57.

1 But if we have a higher -- essentially a
2 higher probability that the SCSR is going to fail, and
3 a low probability of finding the escapeway, the chance
4 of failure in getting out is .63.

5 The bottom line and what I am trying to say
6 here is that the fault tree emphasizes how little just
7 a few changes impact the overall result. Here
8 basically we have reduced our SCSR error.

9 We found a high probability of finding the
10 escape way, and all we have done is improve the
11 chances of getting out, or rather improve the chances
12 of getting out -- or actually this is the chance of
13 failure. Basically, we have lowered the chance of
14 failure from .63 to .57.

15 DR. WEEKS: I am a little lost here. Where
16 do these numbers in the middle come from?

17 DR. KISSELL: This is the top event on the
18 fault tree.

19 DR. WEEKS: And how did you get this?

20 DR. KISSELL: Basically through the process
21 that I showed you before. Basically, calculated from
22 sub-events on the fault tree.

23 DR. WEEKS: What is it that goes before the
24 .63? I mean, I want to put some numbers out there,
25 equals .63, and what is that number?

1 DR. KISSELL: That is the probability of not
2 getting out.

3 DR. WEEKS: And where did it come from?

4 DR. KISSELL: The calculation that we did in
5 the fault tree. In other words, basically we entered
6 --

7 DR. WEEKS: What do these margin numbers do?

8 DR. KISSELL: This is basically the starting
9 events in the fall tree, the probability of finding
10 the escapeway. In other words, basically we entered
11 so-called starting events into the bottom of the fault
12 tree.

13 One starting event, for example, is the
14 quality of SCSR training, and whether the SCSR is
15 going to fail, and whether the AMS system is going to
16 work, whether the stoppings are going to leak, whether
17 in fact people are informed in time.

18 DR. WEEKS: So the path for the .1 and the
19 .93 to the .63 is somewhere else?

20 DR. KISSELL: Right. It is all basically
21 all in one tree, and this essentially, we are just
22 taking a little segment out of the tree, and trying to
23 illustrate the point that changing just a few factors
24 doesn't make much difference. That is what we are
25 after here.

1 DR. BRUNE: So if I understand this
2 correctly, the probability of escape, or getting stuck
3 in the mine, the reverse of that, is mainly dependent
4 on a functioning SCSR, and not so much on finding the
5 escapeway in the first place. Is that correct?

6 DR. KISSELL: Well, let's say, for example,
7 that our SCSR error is quite low. The probability of
8 -- well, they are about the same. Basically, the
9 chance of not getting out, you can reduce it from .63
10 to .57.

11 If your SCSR error is low, the probability
12 of finding an escapeway is high. You can change it,
13 but basically if the probability of finding the
14 escapeway is high, you can improve by an equal amount
15 essentially by changing your SCSR error. So this is
16 pretty -- they are about the same.

17 DR. WEEKS: What makes those numbers go
18 higher or lower?

19 DR. KISSELL: I will come to that.

20 DR. WEEKS: Okay.

21 DR. KISSELL: I will come to that. They are
22 not very optimistic numbers, okay? That's what I am
23 saying. You can also do something in a fault tree
24 called obtain a minimum cut set, and a minimum cut set
25 is the smallest sequence of events leading to failure

1 at the top event.

2 In other words, not getting out, and we
3 found that in minimum cuts that fatality events had
4 common features. First was the delayed evacuation.
5 The second was the lack of lifelines. The third is
6 confusion in locating the escapeway, and the fourth is
7 malfunction of an SCSR.

8 Now considering what we have learned in the
9 last 15 years, this seemed to be reasonably accurate.
10 Now there are other events that involve five or six
11 items that essentially lead to a fatality.

12 But the value of the fault tree here
13 basically is giving us a general perspective on
14 things, rather than a specific perspective, and the
15 general perspective here is that when it comes to
16 escape from mines, people have always been looking for
17 a silver bullet, a great white hope, and at first
18 maybe it was a self-rescuer, and then it was
19 atmospheric monitoring systems.

20 Now it is maybe belt air, or maybe it is
21 something else, and the message from the fault tree is
22 essentially what it takes to make substantial
23 improvements in escape are a number of things working
24 together. Not necessarily one big change, but rather
25 modest changes in everything.

1 And unfortunately we have implemented
2 lifelines, and we will have less confusion in locating
3 the escapeway. Malfunction means poor training. We
4 have had better SCSR training over the years. So I
5 think we have seen some improvements in this already.

6 DR. TIEN: Fred, are you assigning them with
7 equal weight, or are you listing them in the order of
8 significance?

9 DR. KISSELL: It was hard to worry about
10 significance in this particular study, because
11 remember that for the starting events in the fault
12 tree, we had to establish essentially arbitrary
13 probabilities rather than get them from some data.

14 And what we are depending on here are the
15 changes in probabilities, the 10 percent change, the
16 15 percent change, and the probability to draw our
17 conclusions.

18 And under those circumstances it was really
19 hard to draw some conclusion here, with one exception.
20 Delayed evacuation showed up everywhere. If you were
21 to put your thumb on one particular thing, and I think
22 as you read the accident reports that have taken place
23 over the years, even the most recent one, delayed
24 evacuation was a common feature everywhere.

25 DR. WEEKS: That is almost the pathology. I

1 mean, the reason that you didn't get out of the mine
2 is because you stayed in the mine.

3 DR. KISSELL: Well, yes, but that is also
4 true for fires everywhere. People who delay getting
5 out of their house because the house is on fire, and
6 because they wanted to save a pet, or they wanted to
7 go back and recover their wallet, or their pictures of
8 relatives, end up dying in the fire.

9 DR. WEEKS: Well, you could practically
10 blank order some of these features. You can say, yes,
11 all of them together makes (sic) a difference, but
12 some of them are necessary, like evacuation.

13 DR. KISSELL: Well, we are going to deal
14 with rank order in the next study, but it deals a
15 little more powerfully with that issue. And I see the
16 value of the fault tree here. The main value of the
17 fault tree is essentially pointing out that there is
18 no silver bullet here.

19 There is no magic solution that you can put
20 your foot on and say now I have taken care of it. It
21 just is not going to happen. And just to close up, I
22 wanted to point out -- and your questions really in
23 some ways spoke to this, reducing the top event.

24 In other words, if there is a chance that
25 you are not going to get out, and this is one typical

1 example. I am not saying that this is the only way to
2 reduce the top event. Other than delays, you can
3 change these factors.

4 But reducing the top event by 75 percent
5 required for our particular fault tree -- one, minimal
6 delays; an excellent chance to finding the escapeway;
7 excellent SCSR training; and stopping the resistance
8 to smoke leakage and fire damage. That reduced the
9 top event by 75 percent, which is the kind of thing
10 that I think we are looking for.

11 Conclusions. With the exception of delays,
12 single factor changes have minimal impact. That is
13 essentially the conclusion from the fault tree
14 studies. Yes?

15 DR. TIEN: Can you go back to the previous
16 slide. The last sentence, I was a little bit unclear
17 on that.

18 DR. KISSELL: Stopping resistance to smoke
19 leakage and fire damage. Well, clearly if the
20 stoppings leak, then you will have more smoke and more
21 fumes into the escapeway, yes. The ultimate was at
22 Aracoma, where there was no stoppings.

23 DR. WEEKS: Let me nitpick a bit here. With
24 the SCSR, you are assuming that they were; is that
25 right?

1 DR. KISSELL: Yes. We didn't build that in.

2 DR. WEEKS: You didn't build that in?

3 DR. KISSELL: We didn't build that in. We
4 just assumed that they were, which of course is an
5 approximation. Any more?

6 (No response.)

7 DR. KISSELL: Okay. Keep the word delays in
8 mind, because in some ways the most interesting study
9 is coming up, and it really revolves around delays as
10 an issue.

11 And this was a more explicit attempt to rank
12 factors impacting survival during mine fires. It was
13 a study that I did in conjunction with Bob Timko and
14 Dave Litton. And the idea for this study came from a
15 paper written by a guy named Roberts, who worked for
16 the British Coal Board, who published a paper in South
17 Africa, called the Systematic Strategy for Assessing
18 Fire Protection Measures.

19 And what Roberts did is he established an
20 equation to calculate what he called a survival index.
21 And his survival index was basically -- and the unit
22 by the way here of survival index is minutes, and the
23 survival index is essentially the time it takes for
24 the toxic gases to reach the miners, minus these three
25 factors.

1 And the factors are the detection time for
2 the fire, the decision time to decide to get out, and
3 the travel time for the miners to reach a point out by
4 the fire where there would be safe.

5 So basically as these varied, hopefully the
6 combination of the three, these three times, was less
7 than the T-Toxic, and the survival index would be
8 positive, but it was really in my mind a fairly good
9 start in trying to figure out whether or not you had a
10 safe mine, and what contributed to the safe mine.

11 This was as far as Roberts took it, and as I
12 looked at this, I thought to myself, well, this is a
13 good start, but what about atmospheric monitoring
14 systems, and what about stopping leakage, and what
15 about whether or not you wear a self-rescuer, and what
16 about whether or not you have lifelines.

17 What about all the other factors that are
18 important in the escape of mine fires. Could I
19 convert these into time. Could I convert stopping
20 leakage into an equivalent time. Could I convert
21 whether or not you wear a self-rescuer or use a
22 lifeline into an equivalent time.

23 If I could convert all of these things into
24 time. Now, on the basis of time, I could do a
25 comparison between various alternatives in terms of

1 escaping from a mine fire. This way I could
2 essentially optimize the system.

3 And in this regard, this was a system study
4 that tied together the elements of the system
5 mathematically. Now can I equate stopping leakage and
6 translate that into time?

7 Well, it turned out that I could. Could I
8 translate mine fire growth into time? It turned out
9 that I could, and let me give you an example of how
10 this works.

11 Let's imagine a fire growth curve, and here
12 basically on the X-axis, and that is for measuring
13 time, and on the Y-axis, on the ordinate, we are
14 measuring either carbon monoxide or we are measuring
15 the optical density of the smoke.

16 And you can see basically as the fire grows
17 the carbon monoxide or the optical density of the
18 smoke go (sic) up. Now this is one fire growth curve.
19 Now let's say by one way or another we are able to
20 reduce fire growth.

21 Now, the question now becomes what is
22 inhibiting us from getting out of the mine. Let's
23 say, for example, the major barrier for getting out of
24 the mine safely is the optical density of the smoke.

25 So basically this is our criterion in terms

1 of optical density. Well, you can see now with this
2 fire growth curve versus this fire growth, if we
3 reduce the fire growth, here is our time saved.

4 So now we have been able translate a change
5 in fire growth into time, and now we can do a
6 comparison of that time with the other times that we
7 have.

8 Now, I will show you something else, too,
9 that is kind of interesting. Let's say, for example,
10 that we have been able to implement lifelines. So now
11 the optical density of the smoke is no longer our
12 limitation to escaping. We are not wearing self-
13 rescuers yet. I will deal with that later.

14 And now our limitation basically is the
15 carbon monoxide concentration that prevents us from
16 getting out. Now essentially you can see if we
17 implemented lower fire growth rate, and we have
18 implemented lifelines, and instead now we can go to
19 the carbon monoxide level, and our time saved is this.

20 So now we see some sort of synergistic
21 effect between the implementation of lifelines, and we
22 can now use the CO criterion instead of the optical
23 density criterion, and we have seen a synergistic
24 effect between that and the fire growth rate.

25 Usually when people use the word synergy, I

1 roll my eyes and think that they are blowing smoke,
2 but in this case, in fact we are seeing something in
3 the way of something that could be called a
4 synergistic effect.

5 Now a little more complicated for leakage,
6 but nonetheless reasonably straightforward -- and I
7 apologize for this because now is on the Y-axis, and I
8 changed the curve around.

9 And I am plotting leakage versus time from
10 the start of the fire, and I am implying that leakage
11 model that I showed you earlier that I talked about
12 and told you to remember.

13 And essentially what this says now is that
14 if our leakage is 10,000 CFM, we have roughly 20
15 minutes before you lose visibility. If the leakage is
16 2,000 CFM, we have 29 minutes before we lose
17 visibility.

18 Now what we have been able to do is we have
19 been able to say, oh, if we can reduce leakage from
20 10,000 to 2,000, we have saved nine minutes before we
21 run out of visibility.

22 So we have now succeeded in converting stopping
23 leakage into time, and so we can compare the impact of
24 stopping leakage with these other things that we have
25 converted to time as well. Now let's implement

1 lifelines.

2 DR. WEEKS: Let me ask a question at this
3 point. Suppose there is a fire, and there is leakage.
4 You have got a choice. You might fight the fire, or
5 you might escape, or you might stop the leakage. I
6 think stopping the leakage is pretty far down the
7 list. And if there is a fire, there is a chance that
8 the --

9 DR. KISSELL: Well, we are not talking about
10 stopping the leakage after the fire takes place. We
11 are talking about building better stoppings.

12 DR. BRUNE: Or you could talk about closing
13 a door.

14 DR. KISSELL: Pardon me?

15 DR. BRUNE: You could talk about closing a
16 door.

17 DR. KISSELL: Yes.

18 DR. BRUNE: And that would be an immediate
19 impact on stoppage.

20 DR. KISSELL: We are talking about basically
21 better stoppings constructed right from the start.
22 But suppose, for example, that we have employed
23 lifelines.

24 Now that we have lifelines, we don't have to
25 worry so much about the smoke visibility problem, and

1 I establish here rather arbitrarily 160 part per
2 million CO criterion, with a visibility of 1.6 feet,
3 and here is that criterion right here.

4 Now with the implementation of lifelines,
5 even with a 10,000 CFM leakage, we have gained 15
6 minutes here before we reach the 160 part per million
7 CO criteria.

8 So we can essentially say now with lifelines
9 that we have bought 15 minutes. With lifelines, and
10 lower leakage, we have bought a lot more than 15
11 minutes.

12 DR. MUTMANSKY: Fred, there is one thing
13 wrong with that. When you are walking out of the
14 mine, and the smoke becomes thick, and you start using
15 your lifelines, before you do that, you are likely to
16 put the SCSR on immediately.

17 And that curve right there is not going to
18 help that miner, and his decision making is probably
19 going to be made the moment he sees billowing smoke or
20 whatever it happens to be.

21 DR. KISSELL: Yes, but what this says is
22 that he can get a lot further outby before he ever
23 sees smoke.

24 DR. WEEKS: Oh, okay. I understand. My
25 fault.

1 DR. MUTMANSKY: He is buying time.

2 DR. KISSELL: That is the whole story here,
3 is buying time, right. We can see from this curve
4 also basically the 60 minutes that are available. And
5 down here, I have not assumed that we have used the
6 self-rescuer yet, and I have assumed now with the
7 self-rescuer that essentially we have 60 minutes
8 available from lifelines in combination with the self-
9 rescuer.

10 So essentially we have bought 20 minutes
11 originally at a high leakage rate, and another 60 in
12 combination with lifelines in combination with a self-
13 rescuer. So what we have done here is essentially
14 convert all of these things to time.

15 DR. BRUNE: Excuse me, but let me go back
16 one slide, please. How do you come up with the 60
17 minutes from lifelines with SCSR? Shouldn't that be
18 going to the black curve on the top there?

19 DR. KISSELL: That is the fifteen hundred
20 part per million CO criterion.

21 DR. BRUNE: Yes, and how do you come up with
22 this -- are you saying 60 minutes is because the SCSR
23 has 60 minutes time?

24 DR. KISSELL: Yes.

25 DR. BRUNE: Okay. Thank you.

1 DR. KISSELL: That's it. I'm sorry that I
2 didn't make that clearer.

3 DR. WEEKS: But that is from the time that
4 you put it on?

5 DR. KISSELL: Yes. I am assuming that you
6 put it on when you hit smoke, and that's right here.

7 DR. WEEKS: And I think what Jan is
8 suggesting is that you probably would put it on before
9 then.

10 DR. KISSELL: But let's say you put it on
11 here, here halfway out, you are not going to put it on
12 right at the beginning. I don't think that is a
13 practice for people. And putting it on here halfway
14 out, you would probably lose at least 10 minutes off
15 this.

16 But frankly that is another issue, too, is
17 what are the guidelines, and when to put on your self-
18 rescuer. In my book, basically the guideline ought to
19 say that when you see smoke, put on your self-rescuer,
20 because if you don't see smoke, you are not going to
21 get much CO.

22 In fact, until your visibility declines to
23 about four or five feet, you are not going to have
24 much CO. So you can really maximize life on your
25 self-rescuer by waiting.

1 DR. WEEKS: And that is not a part of the
2 training.

3 DR. KISSELL: I know. This whole
4 relationship between smoke and CO is something that is
5 really not been appreciated very much. Now that
6 people have died as a result of getting lost in smoke,
7 and it is very apparent that has happened, there is
8 more understanding of this.

9 But it is just a shame that that had to
10 happen before people moved on it.
11 It is very unfortunate. Anyway, I have been able to
12 translate into time a number of factors.

13 DR. WEEKS: Just a thought.

14 DR. KISSELL: Sure.

15 DR. WEEKS: Part of the potential doctrine
16 about training for CO is that it is odorless and
17 colorless, and you can't protect against it, which
18 paramounts against the direction in which you are
19 headed, which is look for smoke, but look for
20 something that is visible. But I would say that
21 should be deemphasized.

22 DR. KISSELL: I would promote that, yes, but
23 basically what you have learned as a youth or earlier
24 on in your career, is hard to change. You see, the
25 other thing that has happened is that mine rescue

1 teams have gone in after fires, a couple of days
2 later, and essentially they have run into virtually no
3 smoke and high CO levels.

4 And so my contention that there is a
5 relationship between CO and smoke, and CO level is
6 very low at considerable density, smoke densities,
7 goes against that grain. But if you go into a fire
8 later the smoke has settled out.

9 I think if you filled this room with smoke,
10 it would be settled out in an hour or two. Fairly
11 quickly, but that doesn't help people trying to escape
12 from the mine fire, because the fire is burning when
13 they are on the way out.

14 DR. WEEKS: If a guy is inside the mine for
15 an hour or more, than the guideline about if there is
16 smoke, there is CO, and if there is no smoke, there is
17 no CO, that is not true.

18 DR. KISSELL: It falls apart, yes. We are
19 talking about people who are trying to escape, and I
20 have not done any smoke settling studies, and so it
21 may be more than a couple of hours. But clearly it
22 takes place.

23 DR. MUTMANSKY: Fred, did you actually do
24 Stokes law on smoke particles to see how quickly they
25 would settle?

1 DR. KISSELL: No, I haven't done that.

2 DR. MUTMANSKY: I was just going to say that
3 my opinion would be that it would be much longer than
4 that, but I would guess that most of the smoke would
5 be out of the mine anyway due to ventilation movement
6 by the time that anybody went in two days later
7 anyway. So I wouldn't suspect that there would be a
8 lot of smoke still remaining in the mine.

9 DR. KISSELL: But the CO would be out also.
10

11 DR. MUTMANSKY: What was that, Fred?

12 DR. KISSELL: The CO would be out also, and
13 this comes from the experience of mine rescue teams.

14 DR. MUTMANSKY: Right. You're right.

15 DR. KISSELL: And they are going ahead of
16 the ventilation, too.

17 DR. WEEKS: But if there is some low grade
18 combustion, there is going to be CO.

19 DR. KISSELL: Yes, and smoke. In fact, you
20 will notice from the thing that I showed you early on
21 in the smoke paper was that there is more smoke in a
22 smoldering fire per unit of CO than there is in a
23 flaming fire.

24 DR. BRUNE: One more point. I think we need
25 to distinguish between smoke or CO produced from a

1 fire, and CO produced from an explosion. After an
2 explosion, you could probably have at least in my
3 opinion much higher levels of CO without similar
4 levels of smoke.

5 So this relationship does not hold true, and
6 in an explosion case, I would put on my SCSR
7 immediately.

8 DR. KISSELL: That's correct. We deal with
9 mine fires here.

10 DR. BRUNE: Yes.

11 DR. KISSELL: Okay. Here is what we have
12 done translating into time. The replacement of the
13 thermocouple sensors by CO sensors, 6 to 10 minutes;
14 CO alarm threshold, changing it from 15 to 10 parts
15 per million, three minutes.

16 Sensor spacing from 2,000 to 1,000 feet,
17 less than five minutes. Stopping leakage, down 80
18 percent, a rather unrealistic figure. Only nine
19 minutes.

20 Walking out versus riding out, 5,000 feet,
21 10 to 20 minutes, depending on the height of the coal.
22 That is a good way to save time. Decreasing the fire
23 growth rate, 75 percent, saved nine minutes.
24 Lifelines without an SCSR, 15 minutes; with the SCSR,
25 60 minutes, depending of course when you put the SCSR

1 on.

2 So what we have done here is we haven't been
3 able to bring in every possible factor, but we have
4 been able to bring in a lot of factors and translate
5 these into time, and make some estimate of the time
6 that we can save if we deal with that particular
7 issue.

8 Now in the next few slides, I am going to
9 deal with fire growth rate down 75 percent, and talk
10 about this so-called synergy that we saw before. But
11 under the circumstances that we laid out in the
12 initial run, we only saved nine minutes by decreasing
13 the fire growth rate.

14 DR. WEEKS: Well, just to point out the
15 obvious. The gain that you get is from lifelines.

16 DR. KISSELL: Yes.

17 DR. WEEKS: Combined with SCSR?

18 DR. KISSELL: Yes. Well, yes, lifelines
19 combined with SCSR, and walking versus riding. That
20 is not an insignificant factor, too, especially in
21 relatively low coal.

22 DR. KISSELL: We are going to look more
23 extensively at fire growth rate, down 75 percent that
24 we saw on the last slide, change, nine minutes. Okay.
25 Now with the lower fire growth rate, our CO alarm

1 threshold, by changing it from 15 to 10 parts per
2 million, now instead of saving three minutes, it saves
3 12 minutes. And with lifelines and leakage down 50
4 percent, it saves 56 minutes.

5 So basically SCSR, in combination with
6 lifelines, aren't really the only way to save
7 considerable amounts of time. A fire growth rate down
8 75 percent, and leakage down 50 percent, we have got
9 56 minutes from that with lifelines, not even using a
10 self-rescuer. So there are other ways --

11 DR. WEEKS: That puts a numerical value on
12 the most primitive question, which is to say fight the
13 fire or leave, right?

14 DR. KISSELL: Well, basically what happens
15 is that if you are fighting a fire, everybody
16 obviously inby should be moved outby the fire. That
17 is the first order of business, even before fighting
18 the fire.

19 Our conclusions here essentially from this
20 study and the previous studies is that, first of all,
21 multiple factor changes have the most impact. There
22 is no one single silver bullet that you are going to
23 be able to employ.

24 The other is that I think you should
25 consider so-called non-technical factors, such as

1 training and management practices, because those
2 impact the delay, and the delay still remains the most
3 significant factor here. That's where I am coming
4 from. Now what is the relevance of these to belt air
5 and belt flammability.

6 DR. WEEKS: Before we go on, it is a logical
7 extension of your presentation, but kind of outside
8 the boundaries of our this panel's concern, but I
9 didn't see anything about rescue chambers.

10 DR. KISSELL: I didn't get into that. The
11 research really -- well, rescue chambers were never on
12 the table when I did this research. And I would have
13 to think about that a lot more before I said
14 something.

15 DR. WEEKS: All right.

16 DR. KISSELL: What is the relevance of these
17 to belt air and belt flammability? In terms of belt
18 air, the relevance is limited because of other
19 factors.

20 Forbidding belt air has some serious
21 downsides, particularly with regard to the loss of
22 ventilation quantity and velocity, and will negatively
23 impact methane and dust. So I really didn't deal with
24 belt air at all.

25 With regard to belt flammability, this is a

1 fire growth rate issue, and I talked I think rather
2 extensively about fire growth rates, and so you can
3 probably get a notion of where that stands with regard
4 to belt flammability. That is really all I had to
5 say. Any more questions?

6 DR. TIEN: Can you go back to the previous -
7 - maybe three or four slides back? This one and also
8 the diagram. Yes, this one. But what are the
9 assumptions again? Can you revisit that? If we are
10 going to look at this one, can I take this one and use
11 it today?

12 DR. KISSELL: Sure.

13 DR. TIEN: What are the parameters? Do you
14 adjust to specific mining conditions, or ventilation
15 systems, or whatever?

16 DR. KISSELL: This is pretty independent.
17 This is pretty independent, and it essentially derives
18 from that model that you saw back there, where there
19 was a fire in an airway, and leakage into an adjacent
20 airway. This is basically derived from that model.

21 And essentially depending on the quantity of
22 leakage, it takes a certain amount of time for the
23 visibility to decline to the 12 foot level, okay? And
24 that is really relatively independent of various kinds
25 of mining conditions.

1 All we are assuming is that there is a fire
2 in an adjacent airway, and that the smoke and fire
3 fumes leak into the airway that the miners are in.
4 That's all. That is the only assumption.

5 And this is the amount of time right here it
6 takes, and let's say with 4,000 CFM leakage, for it
7 essentially to reach the 12 foot -- here we are, the
8 12 foot, 3.7 meter optical density value, we run out
9 of visibility, and this is the time here that it takes
10 to reach 160 parts per million at 1.6 foot visibility.

11 And this is the time that it takes to reach
12 1,500 parts per million, which is corresponding to a
13 two inch visibility.

14 DR. TIEN: You have probably answered
15 already most of my second, if not all of my questions,
16 and that is that this table was written in 1993?

17 DR. KISSELL: In the early '90s sometime,
18 yeah.

19 DR. TIEN: The '90s. Have any of the things
20 that have happened in the past 15 years where you
21 would want to add or subtract anything from this one?

22 DR. KISSELL: No, not that I can see. It
23 was based on a fairly straightforward model that I
24 think applies today. Fortunately, the lifelines have
25 been implemented, and self-rescuer training has

1 improved, and I think self-rescuers are better.

2 So basically things have improved
3 considerably over where they were back in 1990. So
4 that is where the big changes have been, rather than
5 the changes in mining conditions.

6 DR. TIEN: Thank you.

7 DR. WEEKS: The other factor that you didn't
8 include is the number of entries, and when we were
9 talking about using belt air ventilation on the face,
10 it is usually associated with the reduction of the
11 number of entries. Did you factor that in?

12 DR. KISSELL: I didn't. I didn't see any
13 way that I could see through to do that, because
14 basically the model essentially assumed fire in one
15 air way, and leaking into the adjacent air way, and
16 that was the only assumption that I made, which is in
17 some ways sort of a worst case condition. Because if
18 you were two air ways over, then presumably the
19 leakage would be less maybe.

20 MR. MUCHO: If you could go back to that
21 slide, Fred. Let me interrupt and point something out
22 regarding that.

23 DR. KISSELL: Which one?

24 MR. MUCHO: The slide of your model.

25 DR. KISSELL: All right.

1 MR. MUCHO: Let's say that entry on the left
2 where the fire is, is a belt entry, and let's say the
3 entry over here on the right side of that stopping
4 line is the intake escapeway.

5 This presumes that the leakage is from the -
6 - or in this case, the belt into the intake escapeway.
7 In the case of using belt air, we would be pretty
8 assured that our highest pressure entry would be our
9 intake escapeway, and belt entry would be less, and we
10 would have the 50 percent max from the belt entry, et
11 cetera, which would basically dictate that, especially
12 with the resistance of the belt line.

13 So our leakage would be in the opposite
14 direction. So the intake escapeway air would be
15 clear, but the leakage being also clear. So under
16 this scenario, if it was in the belt entry, we should
17 have a cleanout of escape options?

18 DR. KISSELL: Right. Until the fire
19 got big enough to throttle the air flow in that air
20 way, and then --

21 DR. WEEKS: Well, both of those entries blow
22 smoke, and that is your only way out, that's a
23 problem. I mean, unless there is another entry that
24 is clear, you stand a better chance --

25 DR. KISSELL: We could have established

1 another entry over here, and the delay time associated
2 with that. I could have done that, but I didn't.

3 DR. WEEKS: Well, in your spare time, maybe
4 you can. You have spare time now, and --

5 DR. KISSELL: My nursing home computer I
6 could do that on, yes.

7 DR. WEEKS: Well, I think that is a factor
8 that should be included in some way or other about the
9 number of entries. It is simple enough. Conceptually
10 it is simple enough. I don't know how simple it is
11 mathematically.

12 DR. KISSELL: Well, you know, Gary Pittman
13 and I back around this same time tried to get our
14 hands around that issue in some way. I don't know
15 whether it was with a fault tree or some sort of a
16 systems analysis, saying, well, if you run into the
17 smoke, you can go over here, or you can go over here,
18 or you can try this, or you can try that.

19 And we tried to come up with something. You
20 know, this is reasonably straightforward, and we tried
21 to come up with something straightforward that would
22 lead to some sensible conclusions, and we just went
23 around in circles after a while and gave up after.

24 It was just too difficult because there are
25 just too many improbables, because it depends on sort

1 of where the fire is, and what decisions are made with
2 regard to go from one entry to another, where the
3 doors are, whether they can find the doors, and after
4 a while we just -- you know, we tend to work on
5 problems that we can solve in a reasonably short time
6 frame, so as to get a paper out and get on to the next
7 issue, if you know what I mean.

8 DR. WEEKS: Well, you came up with a very
9 primitive estimation of it. You think there is a
10 fire, and you are better off having three entries
11 compared to two to work with, in terms of an efficient
12 escape.

13 DR. KISSELL: Well, wait a minute now.
14 Where is the fire source, in the intake or the return?

15 DR. WEEKS: I don't know.

16 DR. KISSELL: Say a 10 entry system, with
17 just an entry or just an intake and a return, you have
18 a huge pressure between the intake and the return. If
19 you can locate your sources out in the mains so that
20 basically any fire in the mains, for example, leaks
21 into the return, then essentially you can get out
22 under some conditions that have pretty substantial
23 pressures, okay?

24 So I can visualize scenarios that depending
25 on where you put your fire source, and if the fire

1 source leaks directly into the return rather than
2 coming down the intake, then you have huge pressures
3 between the intake and the return airways, and your
4 escape out is pretty good.

5 DR. WEEKS: That's all true, but --

6 DR. KISSELL: It is all factored in what
7 assumptions you make in the beginning.

8 DR. WEEKS: Well, I understand that. I
9 mean, in the event that you have more than one way out
10 of a mine where there is a fire, that seems to me to
11 be inherently safer than having only one way out.

12 It is like you have a burning building, and
13 you have two fire escapes, and you can go this way or
14 that way. It is the classic case of having one fire
15 escape blocked and which would prevent you from going
16 out the other way, and a lot of people died because of
17 it if they didn't have another way out.

18 DR. KISSELL: I would have to simulate it,
19 and I would have to figure out where the fire source
20 was likely to be, and I would have to look at the
21 pressures before I drew the same conclusion.

22 MR. MUCHO: And the counter to that, Fred,
23 is the Marianna mine, the '58 fire, and the fire
24 occurred in the sub-mains, and we had eight entries
25 there, but the fire occurred in the belt entry, which

1 was the highest pressure and the leakage into the
2 other entries made it very difficult to get the three
3 crews out by the fire area.

4 And you know the story of the fire and
5 getting them out took some heroics on some people's
6 part, because all of the entries were contaminated.
7 So there you had eight entries, but because the fire
8 occurred at the highest pressure, and because of
9 leakages, everything was contaminated.

10 DR. KISSELL: Yes. You know, it was once
11 said that for every complicated problem, there is an
12 answer; that it is clear, simple, and wrong. And I
13 would have to simulate it before I believe it, and I
14 have to work out the probabilities, and I would have
15 to look at the starting conditions.

16 DR. WEEKS: I don't understand your
17 hesitation on this, but I am only making a very simple
18 statement, which is that normally the more ways out
19 the better, rather than fewer.

20 DR. KISSELL: It certainly seems that way,
21 but if you don't control the pressures, and if you
22 don't control where the fire sources are, it doesn't
23 make any difference. So the first actions would be to
24 control the pressures and control the fire sources.
25 That is sort of where I am coming from. Yes?

1 DR. GALIZAYA: One question related to the
2 time analysis. Did you do this analysis based on the
3 value of the probabilities, or how exactly did you get
4 this time analysis conclusions?

5 DR. KISSELL: Basically, what we did is that
6 we did a sensitivity analysis on probabilities. We
7 established a number and put a number in, and then we
8 varied that number and varied the alternative numbers
9 to see whether in fact the results made any sense in a
10 common sense way.

11 And what we were relying on here in the way
12 of conclusions is not necessarily the values of the
13 probabilities, or even how much we varied the
14 probabilities.

15 What we were relying on for conclusions is
16 the simple fact that no matter what probabilities we
17 picked, no matter how much we changed the
18 probabilities of any single or small combination, it
19 never made any difference.

20 Our conclusion was basically that if you
21 want to affect a top event, and if you want to lower
22 the probability of not getting out, you have to affect
23 a whole bunch of things on the bottom.

24 So to really get down to it, what numbers
25 that we picked for the individual probabilities were

1 not really all that relevant. It is the fact that we
2 could vary them all over the map, one or two all over
3 the map, and it didn't make much difference.

4 And that is essentially why we concluded
5 that you really have to vary a lot of things. There
6 was no relative comparison, let's say, of CSCRs versus
7 lifelines in the fault tree analysis that we could
8 really depend on, other than the fact that the notion
9 that you sure had to use both. Plus, minimize delays,
10 plus, plus, plus, plus. So we never really relied on
11 any specific probability numbers.

12 DR. WEEKS: How would you take that message
13 and put it in a form that was readily comprehensible?
14 I mean, you said there is no silver bullet, and just
15 putting it in the negative, but also putting it in the
16 positive?

17 DR. KISSELL: Well, it sort of depends on
18 how you see your charge on your panel. Are you
19 dealing only with belt fires, or do you see basically
20 some possibility of implementing things that not only
21 deal with belt fires, but deal with fires in general?
22

23 DR. WEEKS: Actually, we are not just
24 dealing with fires. What we are dealing with is the
25 whole issue of using the belt air entry at the face,

1 and so it is a little different.

2 DR. KISSELL: Well, I mentioned before that
3 this particular model, as we said, doesn't deal
4 directly with using belt entries, okay?

5 DR. WEEKS: That's true, but I am taking the
6 concept as sort of a general concept, and to apply it
7 to a situation. I guess that is an issue for us to
8 decide.

9 DR. KISSELL: Yes. The problem is that I am
10 here to talk about this particular research, and the
11 research really never dealt with belt air, simply
12 because belt air not only impacts the top event, in
13 terms of escape from mine fires, but it impacts other
14 possible events because of the loss of ventilation
15 air.

16 You are raising the chance that methane will
17 be higher, and you are raising the chance that dust
18 will be higher. So it is a much more complicated
19 issue than just a straightforward escape issue, and
20 really beyond my capability of handling this in this
21 kind of a model.

22 So essentially I am not really able to draw
23 much in the way of conclusions about belt air from
24 this topic at all. I am able to draw conclusions
25 about belt flammability, and fire growth rate, which I

1 gave to you.

2 DR. WEEKS: Could we have a copy of his
3 paper?

4 DR. KISSELL: I think you have got them. If
5 you don't, I can get them for you. Is that all? If
6 so, thank you very much then.

7 MS. ZEILER: Thank you, Dr. Kissel. I would
8 like to suggest that we take our 15 minute afternoon
9 break now.

10 (Whereupon, a short recess was taken.)

11 MS. ZEILER: All right. Just a couple of
12 items. One, the Aracoma Mine Number One report has
13 been issued, and copies have been given to the
14 technical study panel members.

15 Panel members will see that there is a disk
16 in the back, and so if for any reason you don't want
17 to haul the entire binder on the plane, we can mail
18 that to you.

19 The next issue on the agenda is a
20 presentation of comments. The National Mining
21 Association and the United Mine Workers of America
22 were offered a chance to be on the agenda at this
23 meeting to comment on the issues before the panel, and
24 unfortunately the United Mine Workers couldn't make it
25 due to prior commitments.

1 But Thomas McNider, the general manager for
2 Mining Engineering for Jim Walters Resources is here
3 to present on behalf of the National Mining
4 Association. And for the panel's benefit, he has got
5 hard copies that I will provide to you at the end of
6 his statement. Thank you.

7 MR. MCNIDER: Good afternoon. Jim Walters
8 Resources and the National Mining Association would
9 like to thank the panel for the opportunity to provide
10 comments concerning the use of the belt air course to
11 transport air to the working face, and the associated
12 belt that is used in conjunction with belt air.

13 And these comments today are going to be
14 strictly related to monitoring and belt air or belt
15 construction materials. And these comments are
16 limited to the composition and fire retardant
17 properties used only in conveyor belt entries where
18 belt air is used to ventilate the working section.

19 Jim Walters received approval for his first
20 101(c) petition for modification of a mandatory safety
21 standard, 30 CFR 75.326, in 1979, at its number four
22 mine.

23 We have been using belt air successfully at
24 all our coal mines since that time. Contrary to the
25 opinion of others, the industry believes that belt air

1 utilization is safe and is in fact much safer than not
2 utilizing belt air.

3 Numerous studies in the safe use of this
4 form of ventilation in mines throughout our country
5 have shown that belt air ventilation provides for
6 positive ventilation on the belt, real time monitoring
7 for contaminants, and better utilization of air course
8 that is available for ventilation.

9 Just like any other facet of mining, belt
10 air must be used responsibly and the safe precautions
11 required where it is used must be adhered to. There
12 has been a considerable amount of discussion in the
13 press and among perceived experts about the Aracoma
14 accident, and how belt air was a contributor to the
15 lack of escape for two miners.

16 I encourage the panel to study the accident
17 report that was just issued today, and by the State of
18 West Virginia Office of Miner Health and Safety, and
19 Training report prior to coming to any conclusions as
20 to the role that belt air played in this tragic event.

21 I think you will find that conditions
22 totally unrelated to the use of belt air hindered the
23 miners' escape. Belt air has been studied many times,
24 each with a positive finding, that belt air is in fact
25 safe for use on the working face.

1 The last such study was completed in 1991 by
2 an advisory committee to the Secretary of Labor, who
3 concluded that ventilation of a working section using
4 air course through the belt entry is safe provided
5 that certain protections are incorporated into its
6 use.

7 In 1996, MSHA initiated a regulatory process
8 to again review the use of belt air, and promulgate
9 regulations as to its use in coal mines. Jim Walters
10 individually and as part of the National Mining
11 Association, has been involved in each study by
12 commenting on its use and offering our mines as sites
13 to be examined.

14 Should the panel be so inclined, we again
15 offer our mines so that you can see firsthand the
16 safety benefits we derive using this form of
17 ventilation.

18 I will now turn to my experience at Jim
19 Walters in the use of belt air, and comment on the
20 various types of belt material that we have used in
21 our mines, and also the monitoring that we use in our
22 mines.

23 These comments reflect our experience at Jim
24 Walter only. Jim Walters mine wide monitoring. In
25 1979, Jim Walters was granted its first petition to

1 use belt air to ventilate the working sections.

2 These petitions required sensitive carbon
3 monoxide sensors to be installed at intervals along
4 the belt, and at other locations linked to a
5 monitoring system that would alert the miners working
6 at the face in the event of carbon monoxide levels
7 rising above designated limits.

8 Early computer systems for accomplishing
9 this were quickly loaded to levels that caused
10 problems for the systems, resulting in numerous false
11 alarms, and high maintenance costs to keep them
12 operating. Because of this, in 1989, Jim Walters
13 decided to design its own mine wide monitoring system.

14 The system was designed to take advantage of
15 existing carbon monoxide sensors available on the
16 market at the time, and through cooperative efforts
17 with American Mine Research, and CONSPEC, intelligent
18 carbon monoxide sensors were designed.

19 These sensors were designed with direct
20 communication to the Jim Walters mine wide monitoring
21 system to eliminate unnecessary interface cards, and
22 it incorporated many new features, such as auto-
23 calibrate and self-testing.

24 The sensors continued to improve and offer
25 very accurate measurements of carbon monoxide even in

1 areas where air velocity is high. Other devices were
2 designed to allow communication to belt controllers,
3 vacuum breakers, power centers, and so forth, and
4 barriers were developed and improved to allow
5 monitoring in areas of the mine requiring permissible
6 equipment. The system was installed at all of the Jim
7 Walters' mines in 1990 and '91.

8 Operation. The original system used three
9 personal computers to perform the various functions of
10 monitoring the sensors, distributing real time
11 information, and reviewing real time or historical
12 data.

13 Several design improvements have been made
14 to the system in the 17 plus years of operation, and
15 yet many of the original components underground are
16 still in service. Some of them are still in their
17 original location without loss of service.

18 One major improvement in the hardware
19 underground, implemented in 1995, was the design of a
20 totally fiberoptic trunk system. This provides noise
21 immunity and isolation that allowed more locations to
22 be monitored and much more reliable communication
23 under all conditions.

24 The system has a proven track record, and
25 many of the ideas designed into the Jim Walters system

1 were adopted as standard by other manufacturers of
2 mine wide monitoring systems.

3 This current system takes advantage of the
4 latest personal computer hardware and software that is
5 used in some pretty impressive performance benchmarks.
6 The system uses an SQL database for storing the
7 information logged by the system, and uses two
8 personal computers operating redundantly to maintain
9 as much uptime as possible in this difficult
10 environment.

11 It is capable of monitoring 32,000 points.
12 One point is equal to the status to be read from a
13 location underground or on the surface, such as the
14 COPPM value from, say, from the number 23 carbon
15 monoxide sensor, or the state of remote switch number
16 two on wesby belt.

17 Each point may be configured in the system
18 as to how often it is read or scanned, and with
19 current system loading of approximately 2,500 points,
20 the system reads on all values every 1.5 seconds.

21 These fast scan times are important to
22 deliver as close as possible to real time information
23 to the control room operator. We have learned through
24 our experience of monitoring everything underground
25 that many times information obtained from equipment

1 can be just as important as the carbon monoxide sensor
2 reading when the operator needs to make a decision
3 during an event.

4 As a matter of fact, the use of mine wide
5 monitoring systems offers the opportunity to operators
6 to monitor many different functions of their
7 operation, which in-turn enhance the safety of their
8 mines.

9 System staffing. The system would be
10 ineffective without proper staffing. At Jim Walters,
11 we have trained control room operators who watch the
12 system 24 hours a day, seven days a week. This person
13 is also the responsible party as required by MSHA to
14 track people's movement in the mine, and to remove
15 people in case of an emergency.

16 There has been quite a bit of talk today
17 about escapeways and escape from the mine, which I
18 think most of you may be familiar with the MINER Act,
19 and there have been quite a few improvements along
20 that line.

21 The monitoring systems can also be utilized
22 as part of the automated tracking system once it is
23 perfected, also as required by the MINER Act. The
24 control room operators are trained to respond to
25 alarms generated by the system and in detecting

1 conditions that may indicate possible problems before
2 they have a chance to escalate into an alarm
3 condition.

4 The system allows for the setting of five
5 levels of alerts to the operator, and these lower
6 level alerts are set below regulated values in
7 critical areas so that investigation can begin more
8 quickly.

9 The system also provides, too, such as
10 graphical representations of sensors or equipment, to
11 help them make quick and accurate decisions. They
12 also have the ability in some cases to control devices
13 underground, such as stopping the conveyors, or
14 removing power from the section.

15 Staffing also includes at least one carbon
16 monoxide technician for each shift, who has the
17 responsibility of keeping the system calibrated,
18 advanced, and in good operating condition.

19 They are trained in the operation of the
20 sensors and other hardware, and calibration, and the
21 requirements of the law for installation. I will note
22 that the systems we have installed are not unique to
23 Jim Walters.

24 While systems are tailored to the
25 environment within which they operate, this practice

1 in the system hardware and software are commonplace
2 among companies that use belt air to ventilate the
3 working section.

4 Summary. Because many operators use belt
5 air, and many petitions were granted, in 1996,
6 regulations were introduced to eliminate the petition
7 process for belt air and apply a more unified standard
8 to the industry.

9 Most of the requirements that were imposed
10 by the final regulations adopted by MSHA have been in
11 practice at Jim Walters for 10 years or more. Through
12 the years, we have monitored many different special
13 conditions, used many special sensors, and the system
14 has been scrutinized by many different parties, and
15 under various sets of circumstances, and still is
16 recognized industry-wide as the leader in the
17 monitoring systems.

18 Now I want to move to fire retardant belt
19 materials. Because of Jim Walters' commitment to
20 safety and the utilization of belt air, we decided to
21 study the use of a belt that was more fire retardant
22 than the commonly accepted 2G belt.

23 Following the Wheelberg Mine fire in
24 December of 1984, where rubber conveyor belting, which
25 was approved under 2G, was suspected of either being

1 the cause or a contributing factor, it was decided
2 that Jim Walters Resources, Mining Division, should
3 reevaluate its conveyor belt specifications in regard
4 to fire resistance characteristics.

5 Based on this study, it was concluded that
6 Jim Walters mining conditions required more stringent
7 conveyor belt fire resistant characteristics than are
8 acceptable to meet MSHA's Schedule 2G requirements.
9 Consideration was given to establishing testing
10 criteria based on Jim Walters' mines unique
11 conditions.

12 However, it was determined that this was not
13 necessary because, one, established standards in other
14 coal mining countries were broad enough to cover our
15 conditions, and, two, new testing criteria would be
16 difficult to ensure compliance with and could be
17 prohibitively expensive.

18 Therefore, the conveyor belt fire resistance
19 regulations in other countries were studied for
20 applicability to Jim Walters' mines conditions. In
21 reviewing the conveyor belt fire resistance
22 characteristics required by other countries, it was
23 decided that none in their entirety met the
24 requirements of our mines conditions.

25 However, each had some particular test which

1 were applicable to our conditions. Therefore, it was
2 recommended that all future conveyor belt purchases
3 meet the following recognized fire resistance test.

4 One, MSHA Schedule 2G, EMNR, which is
5 Canadian specs, or NCB 158 flame test. Two, MNR or
6 NCB 158 drum friction test. Three, NCB 158 propane
7 burner test. Four, the MNR or NCB 158 electrical
8 resistance test.

9 Jim Walters started using a polyvinyl
10 chloride PVC type belt in late 1983, and this
11 continued until 2001. After the proposed belt
12 specifications were released in March of 1989 by what
13 was then the Bureau of Mines, Pittsburgh Research
14 Center for MSHA, Jim Walters started buying what we
15 referred to as new compliance rubber that met these
16 specifications.

17 We purchased and used this belt from
18 approximately 1991 until 1997, and I have attached
19 with the comments for our one mine the purchases for
20 each of the different type belts to give you an idea
21 of how much of that we used, and what the different
22 type belts were.

23 Although both of these belts exceeded 2G
24 requirements for fire resistance and operating
25 characteristics, both type belts created operational

1 and safety issues that led us to return to the 2G belt
2 in 2001. Now I would like to review a few of the
3 operational problems that we encountered.

4 PVC belt materials, Georgia Duct. This belt
5 was extremely tough when new, but aged rapidly. The
6 older it got, the harder and more brittle it became.
7 The surface would crack and the edge cover would break
8 off. It handles coal well, but rock, which we mine a
9 lot of, pitted the surface, which creates a cleaning
10 nightmare.

11 Wet coal slurry would be deposited along the
12 conveyor at every idler, drive, takeup, and pulley.
13 This in every case is viewed as a hazardous condition,
14 and required large amounts of manhours to control.
15 This problem resulted in numerous 75-400 violations
16 for accumulations of coal dust.

17 The belt had little longevity and became
18 hard and brittle with age. When spliced with a
19 mechanical splicer, this belt fared well using nail
20 type flexcose splices, but would not hold well with
21 the staple type, the clipper type splices.

22 The close proximity in which the staple
23 punched through the material caused a zipper like
24 tearing effect directly behind the splice. This
25 failure would occur without warning.

1 The belt became so hard and brittle that
2 cutting it for splicing and repair purposes became a
3 major task. Mechanical cutting tools were bad to
4 break off the blades while cutting the belt for
5 splicing.

6 Utility knives, the most commonly used
7 cutting tool, were very dangerous because of the
8 extreme amount of pressure that had to be applied to
9 this hardened belt.

10 After the belt was run for a while, and the
11 hardening took place, rolling up the belt off of one
12 installation and reinstalling it into another
13 installation, breaks and splits would occur in the
14 fabric.

15 The point where the trouting idler meets the
16 flat idler in a top idler frame, the pressure of
17 material weight at this point would create splits that
18 would run length ways down the belt. This caused the
19 belt to split, and to spill material at a rate too
20 intense to allow you to continue to run it.

21 Large amounts of downtime were incurred
22 while the split portion of the belt was cut out and
23 removed. A large rock went through the split and hung
24 into a trofing frame, hundreds of feet of belt
25 material could be ripped before the problem was found

1 and corrected.

2 Once the edge cover peeled away the material
3 underneath became a major problem. Strings peeled
4 from the inside of the belt and wrapped themselves
5 around every idler in the entire belt system. Large
6 amounts of production time were lost due to having to
7 shut the belt down to de-string the idlers.

8 Fenner spinner class. The first impression
9 of this belt was good, but we quickly learned that
10 longevity became an issue with this belt also. This
11 material didn't harden like Georgia Duct, but it did
12 have most of the same problems.

13 Some of these problems were splice failure,
14 long splits at trofing point, pitted covers, peeling
15 edge cap strings. The spout was much worse than
16 Georgia Duct when it came to length way splitting, but
17 far stronger in retaining mechanical splices.

18 One feature common to both belts, but not
19 mentioned above, is cover losses. This created
20 problems with mechanical fasteners because there
21 wasn't enough cover to recess the splice, allowing
22 scapers and wipers to grab the fastened edge and tear
23 them from the belt.

24 None of the PVC belt materials that we used
25 allowed the use of poly based idlers. This

1 combination creates tracking issues and the belt is
2 very abrasive to metal idlers.

3 Bubble wear was close to double that of a
4 rubber belt. Another problem associated with both
5 types of PVC belt that we used was when the belt would
6 slip in the drive, a white smoke could be driven off
7 that was irritating at very low part per million
8 levels to a person's nose, throat, and lungs, and
9 would not be detected by the carbon monoxide detection
10 system.

11 It is believed that when the PVC belt is
12 heated to lower temperature levels that hydrogen
13 chloride is the gas that is driven off. New
14 compliance rubber, which is the BELT spec, Georgia
15 Duct rubber. This was a very good belt, with strong
16 thick covers that wear very good.

17 It handles vulcanized and mechanical splices
18 well. It stands up well to abuse that heavy materials
19 subject it to. It can be cleaned with a variety of
20 different scrappers without damage to the cover.

21 The major problem with this type of belt is
22 that the chemical makeup of the cover material allows
23 it to retain heat for long periods of time. If this
24 belt is allowed to run out of alignment for any length
25 of time, the shavings that peel off the belt will hold

1 enough heat to create what is referred to as a hot
2 spot.

3 The floor material under the belt used to
4 transfer coal will begin a combustion process, or it
5 could begin a combustion process, and can spread
6 through a large area of your belt entry, and if
7 undetected could even create a fire.

8 A carbon monoxide system detected many of
9 these hot spots while using this type belt. And in
10 sharing these observations and experiences, Jim
11 Walters is not trying to be negative concerning the
12 use of a more fire resistant belt, but is attempting
13 to point out the operational problems that only
14 looking at one aspect, fire resistance of the belt
15 material, can create.

16 One, operational problems as stated above,
17 ultimately lead to safety issues. As new
18 specifications for belt material are developed, the
19 developer of the specification must be cognizant that
20 it does not create a multitude of other problems.

21 In closing, let me again thank you for this
22 opportunity to present these comments on behalf of Jim
23 Walters and the National Mining Association that
24 utilize belt air to ventilate the working section.

25 Our collective experience has demonstrated

1 that this is safe, effective means to ventilate
2 underground coal mines so that necessary precautions
3 can be implemented to ensure that mine safety is not
4 compromised by its use.

5 As you consider the many facets of this
6 issue, we ask that you not view each factor in a
7 vacuum. Rather, it is imperative that you consider
8 the overall safety benefits derived from this
9 ventilation practice, which history has proven can be
10 safely and effectively for the benefit of miner
11 safety. Any questions?

12 DR. BRUNE: May I can start, Tom. Since you
13 have considerable experience with belts that fulfill
14 the highest specifications -- and in fact I commend
15 you guys to exploring that and going into that. But
16 would you be able to tell us, tell the panel, what the
17 cost factors, what the economic factors were of using
18 belt that was adhering to higher specifications.

19 MR. MCNIDER: I am not prepared to do that,
20 Jurgen, but we did pay a premium to go to the next
21 standard, I can tell you that, above 2G. Of course,
22 our company, like I said, we were committed to looking
23 at a higher grade belt, and we did it for about 20
24 years.

25 I can't tell you exactly what the percentage

1 was, but it was definitely more expensive, and we
2 might be able to get that for you, but I will just
3 have to go back and look at that.

4 DR. BRUNE: And that would be an excellent
5 comparison. I mean, if that is something that you
6 could get, or at least give us something, because
7 certainly the economic impact of coming to a more
8 stringent belt requirement is something that this
9 panel needs to consider.

10 DR. WEEKS: Yes, and not only the cost of
11 the belt and its longevity, but at least describe how
12 the belt was splitting and so on, and the durability
13 of the belt.

14 MR. MCNIDER: We definitely -- I think one
15 of the major points that we are trying to present to
16 the panel is that -- and I think that this came out
17 earlier, that I know that the emphasis is on flame
18 resistant characteristics of the belt, and we looked
19 at flame resistance characteristics of the belt.

20 But you also, and like Jim said, and like
21 Goodyear pointed out in their presentation, I think
22 you have to take into consideration all of the
23 different parameters -- and whether you can weigh
24 them, I'm not sure, but durability of the belt -- if
25 the belt will not do the job it is intended to do,

1 then we have not accomplished anything.

2 So we definitely as we look at fire
3 resistant characteristics, we have go to take into
4 consideration will the belt do the job that it is
5 intended to do.

6 And one thing that did come out in this
7 meeting, and there is a distinct difference, I think,
8 between 600 PIW belt, which maybe a lot of operators,
9 if they are using room and pillar type mining, and
10 longwall mines, in our mines the minimum PIW belt that
11 we use is a thousand PIW.

12 We actually go stronger than that, and I
13 think that while the manufacturers talked about high
14 PIW belts -- and that was part of the problem that we
15 had when we used a PVC type belt. It would not hold
16 up to the rigorous conditions of how tensile loads,
17 heavy wear of the mining material that was being put
18 on the belts, especially for longwall type
19 installations.

20 DR. WEEKS: Could you say something about
21 your training of people who are AMS operators?

22 MR. MCNIDER: I think we could better
23 address that, and my understanding is that you guys
24 may come to Jim Walters again. We do have a rigorous
25 training program, especially now that they are the

1 responsible party.

2 They have always acted somewhat in that
3 position at Jim Walters, but now they are the
4 responsible party for the mine. So there is periodic
5 training where we go through an exercise with the
6 control room operators, where we go through escape,
7 and we go through the ventilation of the mine.

8 As a matter of fact, there may be some
9 exercises, and there are other people that can
10 elaborate more on this than I can, that try to make
11 sure that these people are in position to handle an
12 emergency. But we definitely can get into that later
13 on.

14 DR. WEEKS: When you say you periodically
15 check them, how often does that occur?

16 MR. MCNIDER: Jim, I don't want to say
17 because I am not what it is right now. I would rather
18 go back and review that. But I know that it is done,
19 but I can't tell you what frequency it is done under.

20 DR. WEEKS: There is only a portion of the
21 group that is going to be monitored, but I guess I can
22 get the information on that later.

23 MR. MCNIDER: Right. That is something that
24 we can definitely look into. One of the guys that
25 have been involved in our program for years is Randy

1 Watts, and I am sure that he can definitely address
2 those, and any questions along those lines.

3 DR. TIEN: Tom, you have been using belt air
4 since 1979 or 1980, or thereabouts?

5 MR. MCNIDER: Yes, 1979.

6 DR. TIEN: In the course of 28 or 30 year or
7 so, were there any reportable or non-reportable, or
8 anything at all, on the -- well, what kind of learning
9 curve would you provide other mines?

10 MR. MCNIDER: Well, we certainly had
11 instances where we have had or where we had sensors
12 that would alarm, and with early detection, where we
13 knew early on, and that to me is one of the biggest
14 important factors in using an AMS system, and making
15 sure that the AMS system is designed and will do what
16 it is intended to do.

17 I guess one thing is that everybody thinks
18 about the CO sensor, which is the main primary
19 function of the AMS system, but to me it gives you a
20 lot more capability than that. You can monitor flip
21 sequence, switches, land mines which tell you if
22 materials are falling off a belt.

23 It can tell you if a belt is running or not
24 running. As a matter of fact, you could turn the belt
25 on and off if you had to. If you had an event, you

1 can go back, and under the historical program, you can
2 retrack and learn a tremendous amount of information
3 from the computer program that has stored that
4 information.

5 Where did the CO originate, and how fast did
6 it travel, how quick did the alarm go off, and those
7 type of things. You can really go back and review the
8 information, and the knowledge that you can gain from
9 this is tremendous.

10 The other side of the point that I was
11 trying to make is not only do you have the safety of
12 the CO sensors, but you can also tell if a belt has a
13 problem, and what the problem is with the belt. Did a
14 remote take it out, or did something happen around the
15 drive area. Is the belt slipping. There is a lot of
16 information that you can gather using a monitoring
17 system.

18 DR. TIEN: Can you also share with us --
19 well, you have, of course, two mines in operation, and
20 in each mine you have how many faces?

21 MR. MCNIDER: One at each mine, and three
22 continuous miner sections.

23 DR. TIEN: Right. So you have three
24 development units. Can you share with us what kind of
25 a ventilation system in your mines, and was it

1 developed while you were doing that, and the pressure
2 drops, and the whole nine yards.

3 MR. MCNIDER: Yes. On a typical miner
4 section, our longwall panels now are typically 12 to
5 15,000 feet long. We run a split ventilation system
6 belt on the intake, with a primary intake, and two
7 returns.

8 Typically -- and I am going through this a
9 simple way where I can do it in my head, but on an
10 intake, we have an R per thousand of about .2. So if
11 you go up 10,000 feet, that is an R-2, and on the
12 return, if we have a typical resistance of about .3,
13 and so R per thousand, and if you went 10,000 feet,
14 that is an R of about 3.

15 And typically as we develop a panel, once we
16 get out to about 10,000 feet, we would have 125,000
17 cubic feet per minute at the mouth of the section, and
18 about anywhere from 60 to 80,000 across the last open
19 crosscut on the section.

20 So if you said you had a hundred-thousand in
21 each entry, then that gives you a pressure drop on the
22 section of about five inches, not taking into
23 consideration anything -- any consideration like face
24 drops and that sort of thing.

25 So for a 10 to 15,000 foot long panel, you

1 would be looking at a pressure drop probably in the
2 range of maybe -- and I am going to back up a little
3 bit, but depending -- and actually the intake dropped
4 a little less than what I said, but it is about 4-1/2
5 inches, up to as high as maybe six to seven inches on
6 the high side.

7 After we develop, we connect up, and then
8 for our longwalls, what we do is we pull the yield
9 builder at Jim Walters. In other words, the belts at
10 the number two entry, it is facing that entry.

11 Our track is intake, and so the air is taken
12 down the track and the belt, and I know that NIOSH
13 referred to use of the outside entry. Well, that is
14 possible to parallel it on the longwall, but then you
15 have to also take in some things, such as de-
16 gassification.

17 You may have a de-gas line that runs in that
18 entry that has de-gassed the next panel, and so you
19 have to be cognizant, and you might be able to use it,
20 and you may not be able to use it.

21 But then we take air up, and across the
22 longwall panel, and we are required a minimum of
23 55,000 on our longwall. We go across the face, and
24 then back to the tailgate to the bleeders, and up the
25 headgate to the bleeders, and then the tailgate

1 typically is on intake, and then the air comes back
2 and is returned out the other entry.

3 That is typically the way that the sections
4 are ventilated and the longwall.

5 DR. TIEN: For that kind of a setup, what
6 kind of a gas emission are we talking about roughly?

7 MR. MCNIDER: Well, Jerry, we have been
8 doing -- I can tell you that in the early days that
9 belt air was -- one of the things that you definitely
10 had to consider about belt air in my opinion was
11 keeping a positive ventilation on the belt, because
12 you have got to be -- well, keeping a primary control
13 on the belt is important, and if you have dead spots
14 trying to take the air to a return, you have got to
15 be extremely careful about being able to keep that in
16 control.

17 Because if you don't, and if you have got a
18 belt, or if you have got a high gas liberations, then
19 you could have an area that could get into a danger
20 zone with methane fairly easy.

21 But maintaining a positive flow on the belt
22 in my opinion, one, it helps you from the point of
23 view of the ventilation and getting more air to the
24 face like he said, and he was right, because as you
25 look at the leakage factors, you can't say that you

1 just are at an entry and it is the same thing, because
2 really it is not.

3 And of course that is just looking at pure
4 ventilation, and that is not looking at the strata
5 control aspects of it, too. But I guess the beauty of
6 in it from our point of view is that -- and you asked
7 about the methane liberation, and I am getting away
8 from that, but our mines back when I first started,
9 they would liberate in the range of 20 million cubic
10 feet per day for the mine.

11 Today, we are much, much less than that.
12 But we still are gassy enough to where we need -- you
13 know, we are required behind the line curtain 20,000
14 cubic feet of air, and to do that, you have got to
15 have enough ventilation to get -- if you have 20
16 behind the line curtain in certain instances, you can
17 double that because of leakage.

18 So that is 40 to 50 that you have got to
19 have in the last open crosscut. And then when you get
20 back into the section return, you can at least double
21 that again, and if you go 15,000 feet, you are going
22 to probably triple that.

23 So really now as you look at the big
24 picture, we don't have the gas, but if you look when
25 we are cutting the coal, you still need 18 to 20,000,

1 which means you are still back in this same criteria
2 as far as the amount of air you have got to deliver.

3 One other thing along those lines. When
4 you talked about horsepower earlier, when I told you
5 about the section pressure, five to six inches for
6 panel development means that you have got to have a
7 lot of horsepower on the surface to move that kind of
8 ventilation.

9 And we have 3,5000 horsepower fans, and now
10 a lot of that has to do with our depth, and not
11 everybody has to set up that kind of condition, and
12 also how far you keep your shafts in the mine design.

13 So I am just telling you what Jim Walters
14 does, and those fans are operated at about 1,125,000.
15 So that gives you a little bit of the framework, and
16 why we were moved in the direction that we were.

17 DR. TIEN: Well, this is not directly
18 related, but I am just curious as to how much you put
19 on the miner unit, quantity wise?

20 MR. MCNIDER: On the miner, we are required
21 about 18,000 behind the line curtain, but we typically
22 run 50 to 60,000 in the last open crosscut.

23 MR. MUCHO: What do you run in total water
24 gauge on the main fans? It has been a while since I
25 have been there, and I know what you used to run, but

1 I am wondering what you are doing these days?

2 MR. MCNIDER: It still runs anywhere from 15
3 inches or above.

4 DR. GALIZAYA: This is regarding the AMS
5 system. You mentioned 25,000 --

6 MR. MCNIDER: 2,500.

7 DR. GALIZAYA: 2,500. Out of this, what
8 percentage is for CO sensors?

9 MR. MCNIDER: Right. We can talk more about
10 that later. I would say that the bulk is for CO
11 sensors. We do a little bit where I told you that we
12 do monitor some other parameters associated with the
13 belt.

14 We monitor our fans. I think we monitor
15 pumps. But the bulk of it is for -- our primary usage
16 is for the CO sensors, and what is associated with
17 belt air.

18 DR. GALIZAYA: Do you do monitoring cross-
19 checks on shifts, or what exactly is your cross-check
20 monitoring?

21 MR. MCNIDER: Well, you know, you would have
22 on-shift, pre-shift, and each person has to have a CO
23 and a methane monitor. So I guess that would be your
24 cross-check, but we also are required to calibrate the
25 sensors, and like I said, we have a guy where 100

1 percent that is his job, is maintaining the CO
2 monitoring system. It is a technician, one per shift,
3 and their job is to periodically go and pick certain
4 sensors that they calibrate, and check the accuracy.

5 DR. BRUNE: Tom, is that each person in the
6 mine carrying a CH₄ and a CO sensor?

7 MR. MCNIDER: No.

8 DR. BRUNE: Each foreman?

9 MR. MCNIDER: No, that would be a foreman or
10 a fire boss.

11 MR. MUCHO: Just on the issue of CO sensors.
12 It is pretty easy to tell when they start to go a
13 little bit wacky, right? I mean, you have them in the
14 line, and one is not reading the same as the one
15 before or the one after.

16 MR. MCNIDER: Right.

17 MR. MUCHO: And a lot of times when they
18 have started to experience some sort of problem and
19 they are out of calibration, they tend to go way off
20 scale.

21 MR. MCNIDER: Right. Well, you have COs
22 downstream.

23 MR. MUCHO: And it is pretty easy to see if
24 you might have a bad sensor or something is out of
25 calibration.

1 MR. MCNIDER: Right. One thing that I think
2 they can talk about -- and Randy Watts is our guy
3 responsible for that, and he can talk a lot more
4 intelligently about it than I can. But my
5 understanding is that CO sensors have come a long ways
6 since the early days, and the monitoring systems have
7 come a long ways since the early days. Any other
8 questions?

9 DR. GALIZAYA: How long do they last, each
10 sensor?

11 MR. MCNIDER: I really can't say. I would
12 prefer to wait and -- well, I can't tell you off the
13 top of my head.

14 MS. ZEILER: If there are no other
15 questions, thank you very much, Tom.

16 MR. MCNIDER: All right. Thank you.

17 MS. ZEILER: I have the hard copies to
18 distribute to the panel.

19 DR. MUTMANSKY: Okay.

20 MS. ZEILER: I think we are at the point now
21 where we have public input, but I don't believe we
22 have any signed up do we? Okay. Then I defer to the
23 panel, and if you wish to discuss anything further
24 today.

25 DR. MUTMANSKY: On behalf of the panel, I

1 would like to thank our speakers today. We really
2 appreciate the fact that you came here to share your
3 knowledge with us, and we thank you.

4 We will probably -- I think our -- I don't
5 see any reason for us to at this point in time
6 continue the meeting unless you have a reason, Linda.

7 MS. ZEILER: No.

8 DR. MUTMANSKY: I will then essentially say
9 we will get back together at 9:00 a.m. tomorrow. Are
10 there any other procedural matters for tomorrow that
11 you want to discuss, Linda?

12 MS. ZEILER: No, I think that's it. Nine
13 o'clock tomorrow. Great. We stand adjourned.

14 DR. MUTMANSKY: Thank you.

15 (Whereupon, at 4:14 p.m. the meeting in the
16 above-entitled matter was adjourned, to reconvene at
17 9:00 a.m. on Friday, March 30, 2007.)

REPORTER'S CERTIFICATE

DOCKET NO.: --
CASE TITLE: TECHNICAL STUDY PANEL
HEARING DATE: March 29, 2007
LOCATION: Coraopolis, Pennsylvania

I hereby certify that the proceedings and evidence are contained fully and accurately on the tapes and notes reported by me at the hearing in the above case before the United States Department of Labor, Mine Safety and Health Administration.

Date: March 29, 2007
